About This Document

1.1 Overview

1.1.1 Purpose

This document describes the features, architecture, and programming model of the Freescale Vybrid microprocessor (MPU).

1.1.2 Audience

This document is primarily for system architects and software application developers who are using or considering using this device in a system.

1.1.3 Related Resources

Type	Description	Resource
Data Sheet	The Data Sheet includes electrical characteristics and signal connections.	VYBRIDFSERIESEC[1] -, [1]
Reference Manual	The Reference Manual contains a comprehensive description of the structure and function (operation) of the device.	VYBRIDFSERIESRM[1]
Chip Errata	The chip mask set Errata provides additional or corrective information for a particular device mask set.	Vybrid Chip Errata[1]

Table continues on the next page...

Type	Description	Resource
Application Notes	Application Notes are engineering support documents that assist the user in evaluating the operation of a device product line, package type, or general application topic.	• AN4651 [1] - TFT Panel Support in the Vybrid Microcontroller Family • AN4672 [1] - Using the Run-Length Decoding Features on Vybrid Devices • AN4647 [1] - Configuring and Using the 2D-ACE on Vybrid Microcontrollers • AN4635 [1] - Using the Vybrid TCON Module • AN4512 [1] - Quad Serial Peripheral Interface (QuadSPI) Module Updates

1. To find the associated resource, go to www.freescale.com and perform a search using this term.

1.2 Conventions

1.2.1 Numbering systems

The following suffixes identify different numbering systems:

This suffix	Identifies a
b	Binary number. For example, the binary equivalent of the number 5 is written 101b. In some cases, binary numbers are shown with the prefix *0b*.
d	Decimal number. Decimal numbers are followed by this suffix only when the possibility of confusion exists. In general, decimal numbers are shown without a suffix.
h	Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is written 3Ch. In some cases, hexadecimal numbers are shown with the prefix *0x*.

1.2.2 Typographic notation

The following typographic notation is used throughout this document:

Example	Description
placeholder, x	Items in italics are placeholders for information that you provide. Italicized text is also used for the titles of publications and for emphasis. Plain lowercase letters are also used as placeholders for single letters and numbers.

Table continues on the next page...

Example	Description
`code`	Fixed-width type indicates text that must be typed exactly as shown. It is used for instruction mnemonics, directives, symbols, subcommands, parameters, and operators. Fixed-width type is also used for example code. Instruction mnemonics and directives in text and tables are shown in all caps; for example, BSR.
SR[SCM]	A mnemonic in brackets represents a named field in a register. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).
REVNO[6:4], XAD[7:0]	Numbers in brackets and separated by a colon represent either: • A subset of a register's named field For example, REVNO[6:4] refers to bits 6–4 that are part of the COREREV field that occupies bits 6–0 of the REVNO register. • A continuous range of individual signals of a bus For example, XAD[7:0] refers to signals 7–0 of the XAD bus.

1.2.3 Special terms

The following terms have special meanings:

Term	Meaning
asserted	Refers to the state of a signal as follows: • An active-high signal is asserted when high (1). • An active-low signal is asserted when low (0).
deasserted	Refers to the state of a signal as follows: • An active-high signal is deasserted when low (0). • An active-low signal is deasserted when high (1). In some cases, deasserted signals are described as *negated*.
reserved	Refers to a memory space, register, or field that is either reserved for future use or for which, when written to, the module or chip behavior is unpredictable.
w1c	Write 1 to clear: Refers to a register bitfield that must be written as 1 to be "cleared."

Chapter 2
Overview

2.1 Vybrid Platform

This family of devices is Freescale's latest Dual Core offering with ARM® Cortex®-A5 and ARM® Cortex®-M4 based processors for high end industrial and general purpose applications.

NOTE

Throughout this manual, ARM® Cortex®-A5 is referred as Cortex-A5 or CA5. Also, ARM® Cortex®-M4 is referred as Cortex-M4 or CM4.

These devices are highly integrated reducing system cost for target applications. Main features include

- Cortex-A5 @500MHz (1.57 DMIPS/MHz) with TrustZone with 32 KB I-Cache/32 KB D-Cache
- Neon Media Processing Engine (MPE) co-processor and double precision Floating Point Unit (FPU)
- Cortex-M4 @167 MHz with 16 KB I-Cache/16 KB D-Cache
- 1.5 MB on-chip SRAM with ECC on 512 KB SRAM
- Support for LPDDR2/DDR3
- Dual TFT display up to SVGA and optional 40x4 and 38x6 Segmented LCD
- Dual 10/100 Ethernet with on-chip L2 Switch
- Dual USB OTG with on-chip HS PHY and on-chip HS/FS/LS PHY
- Advanced Security supporting Symmetric with on-chip Tamper detection
- Rich set of communication peripherals and general purpose features
- Advanced digital audio support with multiple audio interfaces and hardware asynchronous sample-rate converter co-processor.
- Multiple package options that include 176 LQFP, and 364 BGA

This family of devices is manufactured utilizing 40nm low-power process.

2.2 Feature Set

This family of devices supports the following features:

Table 2-1. Feature Set

Operating Characteristics	• Voltage range 3.0 V - 3.6 V • Temperature range (T_J) -40 to 105 °C • Flexible modes of operation
ARM Cortex-A5 Core	• Up to 500 MHz ARM Cortex-A5 • 32 KB/32 KB I-/D- L1 Cache • 1.57 DMIPS/MHz based on ARMv7 architecture • NEON MPE co-processor • Dual precision FPU • Optional 512K L2 Cache
ARM Cortex-M4 Core	• Up to 167 MHz ARM Cortex M4 • Build-in DSP capability • 16KB/16KB I-/D- L1 Cache • 1.25 DMIPS/MHz based on ARMv7 architecture
Clocks	• 6 Phase Locked Loops (PLLs) • 2 external crystal ocillators (XOSC) • 2 internal RC (IRC) oscillators
System, protection and power management features	• Flexible stop, wait, and run modes to provide lower power based on application needs. • Peripheral clock enable register can disable clocks to unused modules, thereby reducing currents • Low voltage warning and detect • Hardware CRC module to support fast cyclic redundancy checks (CRC) • 128-bit unique chip identifier • Hardware watchdog • External Watchdog Monitor (EWM) • Dual DMA controller with 32 channels (with DMAMUX)
Debug	• Standard JTAG • 16 bit Trace port
Timers	• Low Power Timer (LPTMR) • One Periodic Interrupt Timer (PIT) with 8 channels • IEEE® 1588 Timers (part of Ethernet Subsystem)
Communications	• UART(w/ LIN2.0, ISO7816, IrDA, LON and hardware flow control) • Serial peripheral interface (SPI) • I^2C with SMBUS support • Dual USB 2.0 HS OTG Controller (Supports LS/FS/HS) with integrated PHYs • 4/8 bit Secure Digital Host controller • Dual 10/100 Ethernet with L2 Switch • FlexCAN3
Memory Interfaces	• 8/16 bit DRAM Controller with support for LPDDR2/ DDR3 - Up to 800 MHz data rate • 8/16-bit NAND Flash controller with ECC • 8/16/32 bit External bus (Flexbus) • Dual QuadSPI supporting Execute-In-Place (XIP)

Table continues on the next page...

Table 2-1. Feature Set (continued)

Graphics Display and Video	• Dual Display Control Unit (DCU) with support for color TFT displays up to SVGA • Segment LCD (3V Glass only) configurable as 40x4, 38x6, and 36x8 • Video Interface Unit (VIU) for camera input • Run Length Endoded (RLE) Decoder • Composite Video Decoder supporting PAL and NTSC
Analog	• 12-bit SAR ADC • 12-bit DAC
Audio	• Synchronous Audio Interfaces (SAI) supporting I2S, AC97 and Codec/DSP interfaces • Enhanced Serial Audio Interface (ESAI) • Sony/Philips Digital Interface (SPDIF), Rx and Tx • Asynchronous Sample Rate Converter (ASRC)
Human-Machine Interface (HMI)	• GPIO pins with interrupt support, DMA request capability, digital glitch filter. • Hysteresis and configurable pull up/down device on all input pins • Configurable slew rate and drive strength on all output pins
On-Chip RAM/ROM	• 512 KB On-Chip SRAM with ECC • 1 MB On-Chip Graphics SRAM without ECC • 96KB On-Chip ROM
Power Consumption	• Low power modes (LP/ULPRUN, STOP, LPSTOP1, LPSTOP2 and LPSTOP3)

2.3 Detailed Block Diagram

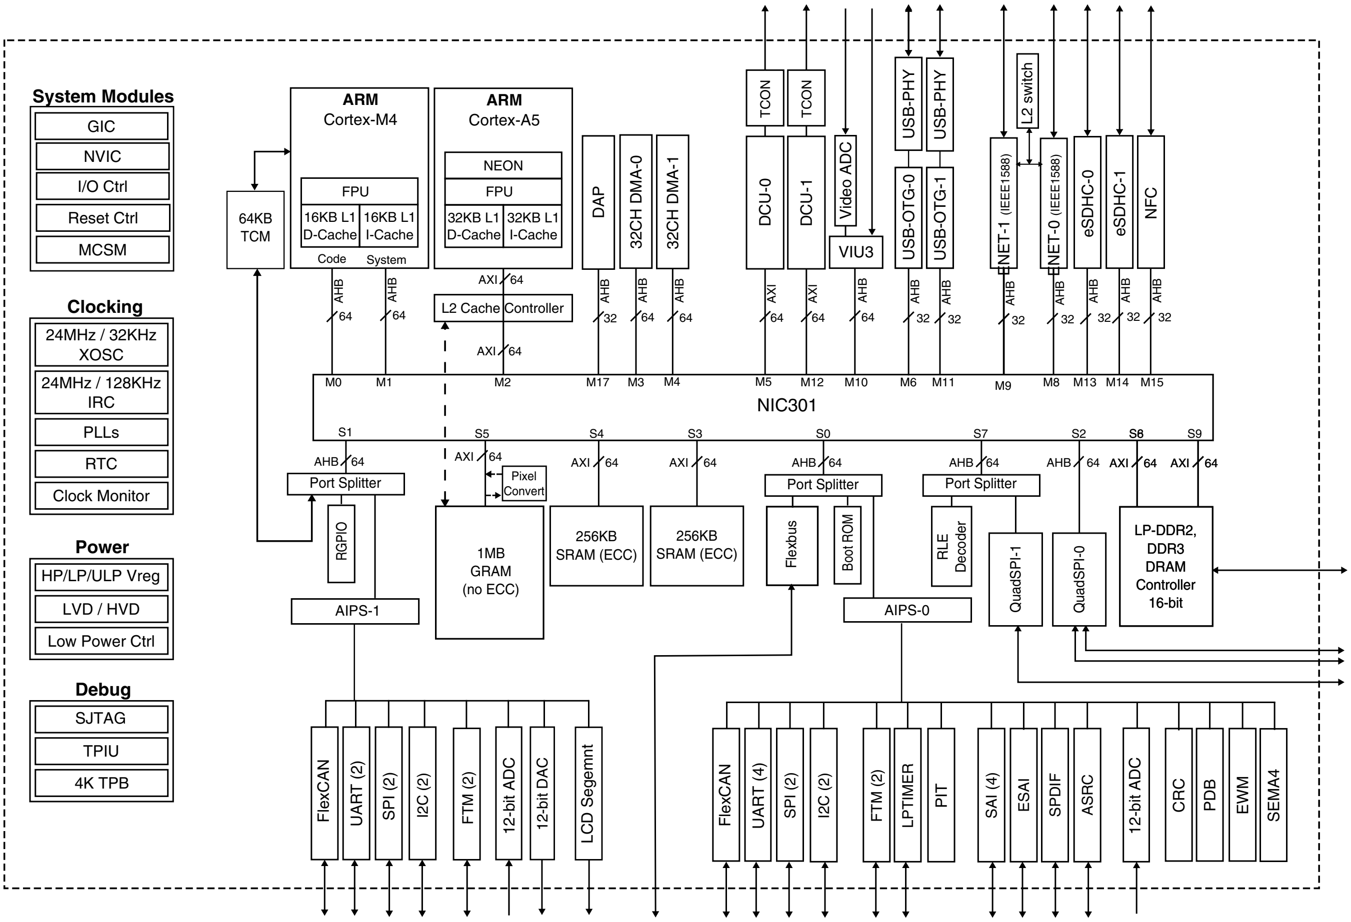

Figure 2-1. Detailed Block Diagram

NOTE

Throughout this manual, ARM® Cortex®-A5 is referred as Cortex-A5 or CA5. Also, ARM® Cortex®-M4 is referred as Cortex-M4 or CM4.

2.4 Device Configuration

The following table lists the superset configuration for each package within the device.

Table 2-2. Device Configuration

Device	VF3XX	VF5XX	VF6XX
General			
Cortex®-A5 Core Frequency	266 MHz	Up to 500 MHz	Up to 500 MHz
Cortex®-M4 Core Frequency	N/A	N/A	Up to 167 MHz
Package	176 LQFP	364 BGA	364 BGA

Table continues on the next page...

Table 2-2. Device Configuration (continued)

Device	VF3XX	VF5XX	VF6XX
Package Dimensions (mm^2)	24 x 24 Pitch (0.5 mm)	17 x 17 Pitch (0.8mm)	17 x 17 Pitch (0.8 mm)
Core, Platform and Debug			
DMA (with DMA Mux)	2 x 32 ch DMA Controllers 4 x 64 to 16 DMA Muxes	2 x 32 ch DMA Controllers 4 x 64 to 16 DMA Muxes	2 x 32 ch DMA Controllers 4 x 64 to 16 DMA Muxes
Trace Port	8 bit Output Trace	16 bit Output Trace	16 bit Output Trace
Security Subsystem			
Random number generator accelerator (RNG)	1, (NIST SP 800-90)	1, (NIST SP 800-90)	1, (NIST SP 800-90)
External Tamper inputs	2	6	6
On-Chip Memories			
On-chip RAM	1.5 MB	1.5 MB SRAM or 1 MB SRAM + 512 KB L2 Cache	1.5 MB SRAM or 1 MB SRAM + 512 KB L2 Cache
ECC on On-chip RAM (512K)	1	1	1
On-Chip ROM	96 KB	96 KB	96 KB
Memory Interfaces			
DRAM Controller (LPDDR2/ DDR3)	No	16 bit	16 bit
NAND Flash Controller	1 (8 bit)	1 (16 bit)	1 (16 bit)

Timers/PWM			
FlexTimer (FTM0) channel pins	8 Ch	8 Ch	8 Ch
FlexTimer (FTM1) channel pins	2 Ch	2 Ch	2 Ch
FlexTimer (FTM2) channel pins	2 Ch	2 Ch	2 Ch
FlexTimer (FTM3) channel pins	None	8 Ch	8 Ch
IEEE® 1588 Timers	4 Ch	8 Ch	8 Ch
Periodic Interrupt Timers(PITs)	4 Ch	8 Ch	8 Ch
Low power timer (LPTMR)	1	1	1
Communication Interfaces			
10/100 ENET with IEEE®1588	2	2	2
eSDHC	1 (8 bit)	2 (8 bit and 4 bit)	2 (8 bit and 4 bit)
FlexCAN	2	2	2
USB 2.0 HS OTG Controller	1	2	2
UART (SCI)	4	6	6
DSPI (16-bit)	3	4	4
IIC	2	4	4

Table continues on the next page...

Table 2-2. Device Configuration (continued)

Device	VF3XX	VF5XX	VF6XX
Display and Video			
TFT Display Control Unit (DCU)	1	2	2
Segmented LCD (40x4)	1	0	0
Video Interface Unit (VIU)	1 ((digital input only)	1 (digital input only)	1 (with digital or analog video input)
RLE Decoder	1	1	1
Analog			
12 bit SAR ADC	2 (12 Ch)	2 (16 Ch)	2 (16 Ch)
Video ADC (Channels)	0	0	4
USB HS PHY (OTG)	1	2	2
12-bit DAC	2	2	2
Audio			
Asynchronous Sample Rate converter(ASRC)	1	1	1
SAI	3	4	4
ESAI	1	1	1
SDPIF	1	1	1
Human Machine Interface			
Total GPIO pins (with Interrupt capability)	Up to 115	Up to 135	Up to 135

2.5 Modules on the device

2.5.1 Clocks

The following clock modules are available on this device.

Table 2-3. Clock modules

Module	Description	Reference links to the related information [1]
Clock Controller Module (CCM)	The Clock Controller Module controls the following functions: • Uses the available clock sources to generate clock roots to various parts of the device • Uses programmable bits to control frequencies of the clock roots • Controls the low power mechanism • Provides control signals to Low Power Clock Gating module (LPCG) for gating clocks • Provides handshake with System Reset Controller (SRC) for reset performance • Provides handshake with Global Power Controller (GPC) for low power mode operations	• Clocking Overview to read about the overall clock distribution on this device. It provides an overview about the different clock sources their typical configuration, and module clocks on this device. • Clock Controller Module (CCM) to read about module features, programing model, Low Power Clock gating, and auxillary clocks on this device.
Analog components control interface (ANADIG)	ANADIG is collection of digital interfaces and controllers of analog components, which include control registers for controlling analog components like device PLLs, PFDs, and regulators.	• Clocking Overview. • ANADIG to read about the registers that control the PLLs, PFDs, and regulators on this device.
Slow Clock Source Controller (SCSC)	Controls the module configures the Slow internal RC oscillator 128 KHz (SIRC) and Slow external crystal oscillator 32 KHz (SXOSC) on the device.	• Clocking Overview. • Introduction Slow Clock Source Controller (SCSC)
Clock Monitor Unit (CMU)	Measures the frequency of clock sources	• Clocking Overview. • Clock Monitor Unit (CMU) to read about module features, programming model, and signals. • CMU Chip Signals section to view the mapping between CMU module signals and the chip-level signals.

1. It is recommended to read the information in the order below.

2.5.2 Platform Modules

The following table lists all platform modules available on this device.

NOTE

Shaded modules are ARM modules. For the detailed description about them, refer to the ARM website.

Table 2-4. Platform modules

Module	Description	Reference

ARM Cortex-A5	The Cortex-A5 processor is a high-performance, low-power ARM macrocell with an L1 cache subsystem that provides full virtual memory capabilities. It supports:
	• ARMv7-A instruction set architecture including
	  • Includes Vector Floating-Point v4 (VFPv4) architecture
	  • NEON Media Processing Engine (MPE)
	  • TrustZone security
	• 8-stage single issue pipeline implementation operating at 266.6, 400-500 MHz speeds
	  • 1.57 DMIPS per MHz integer performance
	  • 4-stage load/store pipeline
	  • 5-stage FPU/MPE pipeline
	• 64-bit AXI System Bus Interface supporting multiple outstanding transactions
	• Processor-local Memories
	  • 2 way set-associative 32 KB Instruction Cache with 32 byte line size
	  • 4 way set-associative 32 KB Data Cache with 32 byte line size
	  • Standard Cortex-A5 Memory Management Unit 64-bit AXI System Bus Interface supporting multiple outstanding transactions
		For ARM Cortex-A5 processor documentation, refer to Cortex-A5 MPCore r0p1 Technical Reference Manual, DDI0434B at http://www.arm.com

CoreLink™ Level 2 Cache Controller	The addition of an on-chip secondary cache, also referred to as a Level 2 or L2 cache, is a recognized method of improving the performance of ARM-based systems when significant memory traffic is generated by the processor. By definition a secondary cache assumes the presence of a Level 1 or primary cache, closely coupled or internal to the processor.	For ARM Cache Controller documentation, refer to DDI0246F_l2c310_r3p2_trm at http://www.arm.com

Table continues on the next page...

Table 2-4. Platform modules (continued)

Module	Description	Reference

ARM Cortex-M4 Core	The Cortex-M4 processor core brings next-generation capabilities to its predecessor, the Cortex-M3. Its new capabilities provide backward compatibility with the Cortex-M3, while adding important features.
	• Supports ARMv7-M instruction set architecture
	  • Includes the single precision FPU
	• 3-stage single issue pipeline implementation
	  • 1.25 DMIPS per MHz integer performance
	• Processor-local Memories
	  • All local memories operate at core frequency and provide 0 wait state response on “hits”
	  • 64 KB of Tightly-Coupled Memory split equally between TCM{Lower, Upper}
	  • 2 way set-associative 16KB CodeCache
	  • 2 way set-associative 16 KB SystemCache
	• Modified Harvard 64-bit AHB System Bus Interface + 64-bit AHB backdoor port to TCM
		For ARM Cortex-M4 processor documentation, refer to Cortex-M4 User Guide Reference Material, DUI0553A at http://www.arm.com

Local Memory Controller	The Local Memory Controller provides the ARM Cortex-M4 processor with tightly coupled processor-local memories and bus paths to all slave memory spaces. The local memory controller includes four memory controllers and their attached memories: • SRAM lower (SRAM_L) controller via the PC bus • SRAM upper (SRAM_U) controller via the PS bus • Cache memory controller via the PC bus • Cache memory controller via the PS bus	

Table continues on the next page...

Table 2-4. Platform modules (continued)

Module	Description	Reference
CoreLink™ System Bus Interconnect (NIC301)	The CoreLink™ Network Interconnect (NIC301) is a 2nd generation highly configurable IP component that enables the creation of a complete high performance, optimized AMBA-compliant network infrastructure. • 1-128 AXI or AHB-Lite slave interfaces for bus master connections • 1-64 master interfaces that can be AXI, AHB-Lite, APB2, or APB3 for bus slave connections • Single-cycle arbitration • Full pipelining to prevent master stalls • Programmable control for FIFO transaction release • Multiple switch networks • AXI or AHB-Lite masters and slaves • Non-contiguous APB slave address map for a single master interface • Independent widths of user-defined sideband signals for each channel • Global Programmers View (GPV) for the entire infrastructure, configurable for customizing the memory mapped visibility • Highly flexible timing closure options	For NIC301 documentation, refer to DDI0397H_corelink_network_interconnect_nic301_r2p2_trm.pdf at http://www.arm.com

ARM Generic Interrupt Controller (GIC)	Generic Interrupt Controller (GIC) is a centralized resource for supporting and managing interrupts in a system that includes at least one processor. It provides:
	• registers for managing interrupt sources, interrupt behavior, and interrupt routing to one or more processors
	• support for the following:
	    • the ARM architecture Security Extensions
	    • the ARM architecture Virtualization Extensions
	    • enabling, disabling, and generating processor interrupts from hardware (peripheral) interrupt sources
	    • Software-generated Interrupts (SGIs)
	    • interrupt masking and prioritization
	    • uniprocessor and multiprocessor environments
	    • wakeup events in power-management environments.
		For ARM GIC documentation, refer to IHI0048B_gic_architecture_specification.pdf at http://www.arm.com

Table continues on the next page...

Table 2-4. Platform modules (continued)

Module	Description	Reference
Debug Interfaces	The device debug and trace is based on ARM CoreSight^{TM} architecture supplemented with the Secured JTAG controller (SJC) to allow security features. Debug interfaces supported are: • IEEE 1149.1 System JTAG Controller (SJC) that provides the security authentication for debug access to the chip. • IEEE 1149.7 JTAG. Also known as compact JTAG (cJTAG). • ARM Serial Wire Debug (SWD) • Support for Secured and non secured invasive/ non invasive debug to allow further granularity in debug accesses. • Support for field return parts to open access for debug and test to allow failure analysis. • Cross Trigger supported between the two cores as recommended by ARM. • Program trace support • Data trace supported by the Cortex-A5	For ARM debug documentation, refer to ARM Debug Interface - IHI0031A_ARM_debug_interface_v5.pdf at http://www.arm.com
eDMA	• 32 channels support independent • 8-, 16-, or 32-bit single value or block transfers • Supports variable sized queues and circular queues • Source and destination address registers are independently configured to postincrement or remain constant • Each transfer is initiated by a peripheral, CPU, periodic timer interrupt or eDMA channel request • Each DMA channel can optionally send an interrupt request to the CPU on completion of a single value or block transfer • DMA transfers possible between memories, General Purpose I/Os (GPIOs) and Slave Peripherals that support DMA • Programmable DMA Channel Mux allows assignment of any DMA source to any available DMA channel with up to a total of 64 potential request sources	Refer to the Direct Memory Access Controller (eDMA) chapter of this manual.
Peripheral Bridge (AIPS-Lite)	• Supports up to 160 peripherals and two global external peripheral spaces • Supports 8-, 16-, and 32-bit width peripheral slots • Supports a pair of 32-bit transactions for selected 64-bit memory accesses • Each independently configurable peripheral includes a clock enable, which allows peripherals to operate at any speed less than the system clock rate.	Refer to the AIPS-lite chapter of this manual.

Table continues on the next page...

Table 2-4. Platform modules (continued)

Module	Description	Reference

Semaphores (SEMA4)	The Semaphores module implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:
	• Support for 16 hardware-enforced gates in a dual-processor configuration
	  • Each hardware gate appears as a 3-state, 2-bit state machine, with all 16 gates mapped as a byte-size array
	  • Optional interrupt notification after a failed lock write provides a mechanism to indicate when the gate is unlocked
	  • Secure reset mechanisms are supported to clear the contents of individual gates or notification logic, as well as a clear_all capability
	• Memory-mapped IPS slave peripheral platform module
	  • Interface to the IPS bus for programming-model accesses
	  • Two outputs (one per processor) for interrupt notification of failed lock writes
		Refer to the IPS_Semaphore chapter of this manual.

2.5.3 System Modules

The following system modules are available on this device.

Table 2-5. System modules

Module	Description	Reference links to the chip related information
Power management controller (PMC)	The PMC provides the user with multiple power options. Ten different modes are supported that allow the user to optimize power consumption for the level of functionality needed. Includes power-on-reset (POR) and integrated low voltage detect (LVD) with reset (brownout) capability.	
Peripheral bridges	The peripheral bridge converts the crossbar switch interface to an interface to access a majority of peripherals on the device.	
DMA multiplexer (DMAMUX)	The DMA multiplexer selects from many DMA requests down to 16 for the DMA controller. There are 2 DMA multiplexers associated with each 32-channel DMA.	DMAMUX Request Sources
Direct memory access (DMA) controller	The DMA controller provides programmable channels with transfer control descriptors for data movement via dual-address transfers for 8-, 16-, 32- and 128-bit data values.	

Table continues on the next page...

Table 2-5. System modules (continued)

Module	Description	Reference links to the chip related information
External watchdog monitor (EWM)	The EWM is a redundant mechanism to the software watchdog module that monitors both internal and external system operation for fail conditions.	
Software watchdog (WDOG)	The WDOG monitors internal system operation and forces a reset in case of failure. It operates on SXOSC 32 KHz clock with a programmable refresh window to detect deviations in program flow or system frequency.	

2.5.4 Memories and Memory Interfaces

The following memories and memory interfaces are available on this device.

Table 2-6. Memories and memory interfaces

Module	Description	Reference links to chip related information

On-chip memory	• The device Includes:
	  • 512 KB On-Chip SRAM with error-correcting code (ECC)
	  • 1 MB On-Chip Graphics SRAM without ECC
	  • 96 KB On-Chip ROM	

Programmable Cyclic Redundancy Check (CRC32)	The module generates 16/32-bit CRC code for error detection. The CRC module provides a programmable polynomial, SEED, and other parameters required to implement a 16-bit or 32-bit CRC standard. The 16/32-bit code is calculated for 8/16/32-bit data at a time. The data width and transpose features are selectable by a parameter.	

Table continues on the next page...

Table 2-6. Memories and memory interfaces (continued)

Module	Description	Reference links to chip related information
DRAM Memory Controller (DDRMC)	DDRMC is a complete embedded memory controller that interfaces to a PHY. The features of this Memory Controller include: • Supports interfacing to LPDDR2 and DDR3 memory types. It supports 8-bit and 16-bit memory interface. • Fully pipelined command, read and write data interfaces to the memory controller. • Advanced bank look-ahead features for high memory throughput. • Front-end interface to 2 standard AXI ports. A programmable register interface to control memory parameters and protocols including auto pre-charge. • Full initialization of memory on memory controller reset. • ECC functionality with single bit and double bit error reporting and automatic correction of single bit error events. 10-bit memory interface is required for ECC (8-bit user data + 2-bit ECC). • ECC functionality with single bit and double bit error reporting and automatic correction of single bit error events. • Clock frequencies from 100 MHz to 400 MHz supported. • Back-end interface to a PHY. • Integrates support for DDR pad calibration logic - both software and hardware auto modes	DDR maximum address space
FlexBus	External bus interface with multiple independent, user-programmable chip-select signals that can interface with external SRAM, PROM, EPROM, EEPROM, flash, and other peripherals via 8-, 16- and 32-bit port sizes. Configurations include multiplexed or non-multiplexed address and data buses using 8-bit, 16-bit, 32-bit, and 16-byte line-sized transfers. Maximum frequency that FlexBus supports is 57 MHz	• FlexBus signal multiplexing • FlexBus external signal • FlexBus security • Instantiation Information • FlexBus Chip Select Control Register (CSCR0) Reset Value • Bus Timeout
NAND flash controller	8-bit and 16-bit NAND flash interface with 32-bit ECC error correction. • Supports all NAND Flash products regardless of density/organization (with page size of 512 K+16B/2 K+64B/4 K +128B/4 K+218B/8 K) • Two Configurable DMA channels • Maximum serial clock frequency 80 MHz	Instantiation

Table continues on the next page...

Table 2-6. Memories and memory interfaces (continued)

Module	Description	Reference links to chip related information
QuadSPI	Interface for up to two external quad serial flash memories for code / data storage and code execution • Supports industry standard single, dual and quad mode serial flashes • Supports Double Data Rate (DDR) serial flash for high performance • Maximum serial clock frequency 80 MHz • Dual controller architecture enables simultaneous access to two external flashes resulting peak read bandwidth of 160 Mbytes/s • Flexible buffering scheme, multi-master, prioritized access	• QuadSPI Instances • QuadSPI Memory Interface • QuadSPI Buffer • Booting from QuadSPI

2.5.5 Audio modules

The following audio modules are available on this device:

Table 2-7. Audio modules

Module	Description	Reference links to chip related information
Enhanced Serial Audio Interface (ESAI)	Provides a full-duplex serial port for serial communication with a variety of serial devices, including industry-standard codecs, Sony/Phillips Digital Interface (SPDIF) transceivers, and other DSPs. The ESAI consists of independent transmitter and receiver sections, each section with its own clock generator.	• Enhanced Serial Audio Interface (ESAI) • ESAI Bus Interface and FIFO (ESAI_BIFIFO)
Sony/Philips Digital Interface (SPDIF)	The SPDIF is composed of two parts: • SPDIF Receiver: The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in the SPDIF Rx left and right FIFOs. The Channel Status and User Bits are also extracted from each frame and placed in the corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter. • SPDIF Transmitter. For the SPDIF transmitter, the audio data is provided by the processor via the SPDIFTxLeft and SPDIFTxRight registers. The Channel Status bits are also provided via the corresponding registers.	

Table continues on the next page...

Table 2-7. Audio modules (continued)

Module	Description	Reference links to chip related information
Asynchronous Sample Rate Converter (ASRC)	Converts the sampling rate of a signal associated to an input clock into a signal associated to a different output clock.The ASRC supports concurrent sample rate conversion of up to 10 channels of about -120dB THD+N. The ASRC supports up to 3 sampling rate pairs. The ASRC is hard-coded implemented, as a co-processor, with minimal CPU intervention.	
Synchronous Audio Interface (SAI)	Implements supports full-duplex serial interfaces with frame synchronization such as I2S, AC97, and CODEC/ DSP interfaces.	• Synchronous Audio Interface (SAI) • SAI3 register details • Simultaneous SAI DMA requests • SAI transmitter and receiver options for MCLK selection • SAI in Stop mode

2.5.6 Timer modules

The following timer modules are available on this device:

Table 2-8. Timer modules

Module	Description	Reference links to chip related information
Programmable delay block (PDB)	• 16-bit resolution • 3-bit prescaler • Positive transition of trigger event signal initiates the counter • Supports two triggered delay output signals, each with an independently-controlled delay from the trigger event • Outputs can be OR'd together to schedule two conversions from one input trigger event and can schedule precise edge placement for a pulsed output. This feature is used to generate the control signal for the CMP windowing feature and output to a package pin if needed for applications, such as critical conductive mode power factor correction. • Continuous-pulse output or single-shot mode supported, each output is independently enabled, with possible trigger events • Supports bypass mode • Supports DMA	• PDB Instantiation • PDB Module Interconnections • DMA support on PDB • PDB in Low-Power modes • PDB implementation with ADC

Table continues on the next page...

Table 2-8. Timer modules (continued)

Module	Description	Reference links to chip related information
Flexible timer modules (FTM)	• Selectable FTM source clock, programmable prescaler • 16-bit counter supporting free-running or initial/final value, and counting is up or up-down • Input capture, output compare, and edge-aligned and center-aligned PWM modes • Operation of FTM channels as pairs with equal outputs, pairs with complimentary outputs, or independent channels with independent outputs • Deadtime insertion is available for each complementary pair • Generation of hardware triggers • Software control of PWM outputs • Up to 4 fault inputs for global fault control • Configurable channel polarity • Programmable interrupt on input capture, reference compare, overflowed counter, or detected fault condition • Quadrature decoder with input filters, relative position counting, and interrupt on position count or capture of position count on external event • DMA support for FTM events	• FTM Instantiation • FTM output triggers for other modules • FTM Global Time Base • FTM Hardware Triggers • FTM Fault Detection Inputs
Periodic interrupt timer (PIT)	• 8 channels • Interrupt timers for triggering ADC conversions • 32-bit counter resolution • Clocked at system clock frequency • 4 channels connected to DMA	• PIT Instantiations • PIT/DMA Periodic Trigger Assignments
Low-power timer (LPTimer)	• Selectable clock for prescaler/glitch filter of 1 kHz (internal LPO), 32.768 kHz (external crystal), or internal reference clock • Configurable Glitch Filter or Prescaler with 16-bit counter • 16-bit time or pulse counter with compare • Interrupt generated on Timer Compare • Hardware trigger generated on Timer Compare	LPTMR prescaler/glitch filter clocking options
Real-time clock (RTC)	• Independent power supply, POR, and 32 kHz Crystal Oscillator • 32-bit seconds counter with 32-bit Alarm • 16-bit Prescaler with compensation that can correct errors between 0.12 ppm and 3906 ppm	

2.5.7 Communication interfaces

The following communication interfaces are available on this device:

Table 2-9. Communication modules

Module	Description	Reference links to the chip related information

Ethernet MAC with IEEE 1588 capability (ENET)	Ethernet Subsystem on Vybrid include the following blocks:
	• Dual 10/100 Ethernet MAC (MAC-NET From MTIP)
	  • Hardware support for IEEE Standard for a Precision Clock Synchronization Protocol for Networked Measurement and Control Systems IEEE 1588
	  • Reduced media independent interface (RMII) support
	  • Interfaces with Unified DMA
	  • Supports wake-up from low power mode through magic packets
	  • Multiple clock source options for time-stamping clock
	• 10/100 L2 Ethernet Switch (From MTIP)
	  • 3-Port Switch
	  • Supports two MAC-NETs
	  • Supports 64-bit Atlantic/FIFO ports and IEEE 1588 support
	  • Fast cut-through mode
	  • QoS with 8-queues per port and port mirroring
	  • Level 3 IP snooping
	• Dual Unified DMA
	  • On-chip transmit and receive FIFOs
		• Instantiation Information
		• MII and RMII configuration
		• IEEE 1588 Timers
		• Ethernet Operation in Low Power Modes
		• Ethernet Subsystem Interrupts
		• Ethernet switch register reset values)

Universal Serial Bus Controller (USB)	USB 2.0 compliant module with support for host, device, and On-The-Go modes. Includes an on-chip transceiver for full and low speeds. The registers and data structures are based on the Enhanced Host Controller Interface Specification for Universal Serial Bus (EHCI) from Intel Corporation. **NOTE:** OTG controller should be treated as Dual role controller that allows the controller to act as either a Host or a device with no support for HNP/SRP.	• USB Configuration and Options • SOF for USB Audio • OverCurrent and VBUS Connection
Controller Area Network (CAN)	Supports the full implementation of the CAN Specification Version 2.0, Part B	FlexCAN Instantiation
Serial Peripheral Interface (SPI)	Synchronous serial bus for communication to an external device	• SPI Instantiation • Number of PCS
Inter-Integrated Circuit (I2C)	Allows communication between a number of devices. Also supports the System Management Bus (SMBus) Specification, version 2.	Instantiation Information
Universal asynchronous receiver/transmitters (UART)	Asynchronous serial bus communication interface with programmable 8- or 9-bit data format and support of CEA709.1-B (LON), ISO 7816 smart card interface	• UART configuration information • UART wakeup • UART interrupts • UART Instances Register Difference

Table continues on the next page...

Table 2-9. Communication modules (continued)

Module	Description	Reference links to the chip related information
Secure Digital host controller (SDHC)	Interface between the host system and the SD, SDIO, MMC, or CE-ATA cards. The SDHC acts as a bridge, passing host bus transactions to the cards by sending commands and performing data accesses to/from the cards. It handles the SD, SDIO, MMC, and CE-ATA protocols at the transmission level.	• SD bus pullup/pulldown constraints • SDHC Wakeup • SDHC Software Guidelines

2.5.8 Graphics Modules

The following core modules are available on this device.

Table 2-10. Graphics/Display Modules

Module	Description	Reference links to chip related information
Display Controller Unit (DCU4)	It is a system master that fetches graphics stored in internal or external memory and displays them on a TFT LCD panel. It supports: • Full RGB888 output to TFT LCD panel • 64 graphics layers, a default background color layer and a cursor layer with integrated blinking option • Blending of each pixel using up to 6 source layers dependent on size of panel • Programmable panel size up to XGA (1024x768) • Gamma correction with 8-bit resolution on each color component • Safety mode for tagging pixels on highest priority layers • Dedicated memory blocks to store a cursor and Color Look Up Tables (CLUTs) • Temporal Dithering	DCU Instantiation

Table continues on the next page...

Table 2-10. Graphics/Display Modules (continued)

Module	Description	Reference links to chip related information
RLE	Decodes data that has been compressed using a Run Length Encoding (RLE) scheme. It has input and output FIFO buffers directly connected to the crossbar switch and requires the CPU or DMA to push in the encoded data and then extract the decoded result. The module configuration is optimized for decoding data stored in a two-dimensional image format but can also be used to extract data stored as a linear array. • 32 channels support independent • 8/16/32-bit single value or block transfers • Supports variable sized queues and circular queues • Source and destination address registers are independently configured to postincrement or remain constant • Each transfer is initiated by a peripheral, CPU, periodic timer interrupt or eDMA channel request • Each DMA channel can optionally send an interrupt request to the CPU on completion of a single value or block transfer • DMA transfers possible between system memories, General Purpose I/Os (GPIOs) and Slave Peripherals that support DMA • Programmable DMA Channel Mux allows assignment of any DMA source to any available DMA channel with up to a total of 64 potential request sources	RLE Instantiation
TCON	The Timing Controller module (TCON) provides an alternative interface for the DCU that provides RGB data and timing signals for "raw" TFT panels which have no embedded TCON. • Flexible timing generation unit supporting 12 timing signal channels • Supports bit mapping of 8-bit or 6-bit color depth • Blanking of RGB data during inactive period (driven to all "0" or all "1")	TCON Instantiation

2.5.9 Analog modules

The following analog modules are available on this device:

Table 2-11. Analog modules

Module	Description	Reference links to chip related information
12-bit analog-to-digital converter (ADC)	It is a successive approximation ADC designed for operation within an integrated microcontroller system-on-chip.	• ADC Instantiation • Voltage reference selection (REFSEL settings) • DMA Support on ADC • ADC Channel Assignments • ADC interconnections
Video ADC	The VideoADC module comprises an analog front end and video decoder block allowing up to 4 composite video sources to be connected. The Video ADC accepts NTSC and PAL format composite video, digitises, filters and decode this video and outputs a digital video stream to the VIU module for further processing.	Instantiation
Temperature Voltage Monitor	It contains the voltage and temperature monitor circuits. These circuits are put into a separate power domain. Its features are: • Low power designs to support the coin battery • Trimmable Voltage and Temperature detector thresholds	
Power Management Unit (PMU)	The PMU of the device includes: • High power or main regulator (HPREG) • Voltage reference for HPREG • Low power regulator (LPREG) • Ultra low power regulator (ULPREG) • Voltage reference for LPREG and ULPREG • Low voltage detector for 3.3V supply • Separate Low voltage detectors for HPREG ,LPREG ,ULPREG output voltages · Power on Reset(POR) • Power up sequencing and testing • N-well bias circuit	

Chapter 3
Memory Map

3.1 System memory map

The following table shows the high-level device memory map.

CM4 Address Range [Start Addr - End Addr]	Size [MB]	CM4 Alias	System Address (A5) [Start Addr - End Addr]	Region Description
0x0000_0000 -0x007f_ffff	8	0x0000_0000	0x0000_0000-0x007f_ff ff	Boot ROM
0x0080_0000-0x0fff_ffff	248	0x8080_0000	Reserved	CM4 DDR code alias
0x1000_0000-0x17ff_fff f	128	0x2000_0000	Reserved	CM4 QuadSPI0 code alias
0x1800_0000-0x1eff_fff f	112	0x3000_0000	Reserved	CM4 FlexBus code alias
0x1f00_0000-0x1f7f_ffff	8	0x3f00_0000	Reserved	CM4 OCRAM code alias
0x1f80_0000-0x1fff_ffff	8	N/A	0x1f80_0000-0x1fff_ffff	CM4 TCML (code)

0x7a00_0000 0x7bff_ffff	32	0x7a00_0000	0x7a00_0000 - 0x7bff_ffff	QuadSPI1 Rx buffer
0x7c00_0000 0x7dff_ffff	32	0x7c00_0000	0x7c00_0000 - 0x7dff_ffff	QuadSPI0 Rx buffer
0x7e00_0000 0x7e7f_ffff	8	0x7e00_0000	0x7e00_0000 - 0x7e7f_ffff	gfxRAM- RGB565 view
0x7e80_0000 0x7eff_ffff	8	0x7e80_0000	0x7e80_0000 - 0x7eff_ffff	gfxRAM-ARGB1555 view
0x7f00_0000 0x7f7f_ffff	8	0x7f00_0000	0x7f00_0000 - 0x7f7f_ffff	gfxRAM-ARGB4444 view
0x7f80_0000 0x7fff_ffff	8	N/A	Reserved	Reserved
0x8000_0000-0xdfff_ffff	1536		0x8000_0000-0xdfff_ffff	DDR
0xe000_0000-0xffff_ffff	512	N/A	Reserved	CM4 Private Peripheral Bus (PPB)
	512	N/A	0xe000_0000-0xffff_ffff	DDR (A5 only)

NOTE

16 KB SRAM on the device occupies upper part of memory assigned to SRAM (0x4007_c000- 0x4007_FFFF)

NOTE

64 KB/16 KB SRAM, which is retained in LPSTOP modes occupies the lower part of OCRAM-SysRAM0

NOTE

For OCRAM-gfxRAM region (0x3f40_0000-0x3f47_ffff), if the "L2 Cache DISABLE " eFuse is blown (L2_CACHE_DISABLE = 1), the entire 1 MB space based at 0x3f40_0000 is allocated to gfxRAM. If L2_CACHE_DISABLE = 0, the first 512 KB (0x3f40_0000 - 0x3f47_ffff) is allocated to gfxRAM and the upper 512 KB is allocated to the L2 Cache data array.

NOTE

If there is an access to reserved/illegal memory space, then the system may hang, requiring a reset to recover. There is no time-out mechanism to recover from this scenario.

3.2 Peripheral Bridge 0 (AIPS-Lite 0) Memory Map

Table 3-2. Peripheral bridge 0 slot assignments

0x400F_F000	Not an AIPS-Lite slot. The 32-bit general purpose input/output module that shares the crossbar switch slave port with the AIPS-Lite is accessed at this address.	

NOTE

Access to non-implemented registers in following modules may not guarantee the device behavior:

- UART
- MLB
- NFC
- IOMUX
- ASRC

- SPDIF
- VIU
- TCON
- USB
- OCOTP
- ANADIG
- SDHC

3.4 Private Peripheral Bus (PPB) memory map

The PPB is part of the defined ARM bus architecture and provides access to select processor-local modules. These resources are only accessible from the core; other system masters do not have access to them.

Table 3-4. PPB memory map

System 32-bit Address Range	Resource
0xE000_0000–0xE000_0FFF	Instrumentation Trace Macrocell (ITM)
0xE000_1000–0xE000_1FFF	Data Watchpoint and Trace (DWT)
0xE000_2000–0xE000_2FFF	Flash Patch and Breakpoint (FPB)
0xE000_3000–0xE000_DFFF	Reserved
0xE000_E000–0xE000_EFFF	System Control Space (SCS) (for NVIC and FPU)
0xE000_F000–0xE004_0FFF	Reserved
0xE004_1000–0xE004_1FFF	Embedded Trace Macrocell (ETM)
0xE004_2000–0xE004_2FFF	Embedded Trace Buffer (ETB)
0xE004_3000–0xE004_3FFF	Embedded Trace Funnel
0xE004_4000–0xE004_4FFF	Cross Trigger Interface (CTI)
0xE005_0000–0xE007_4FFF	Reserved
0xE008_0000–0xE008_0FFF	Miscellaneous Control Module (MCM)
0xE008_1000–0xE008_1FFF	Reserved
0xE008_2000–0xE008_2FFF	Cache Controller
0xE008_3000–0xE00F_EFFF	Reserved
0xE00F_F000–0xE00F_FFFF	ROM Table - allows auto-detection of debug components

Chapter 4
Signal Multiplexing

4.1 Pinouts

The following table shows the signals available on each pin and the locations of these pins on the devices supported by this document. The IOMUX Controller (IOMUXC) Module is responsible for selecting which ALT functionality is available on each pin.

364 MAP BGA	176 LQFP	Pin Name	Default	ALT0	ALT1	ALT2	ALT3	ALT4	ALT5	ALT6	ALT7	EzPort

Chapter 5
Input/Output Multiplexer Controller (IOMUXC)

5.1 Overview

The IOMUX Controller (IOMUXC), together with the IOMUX, enables the device to share one pad to several functional blocks. The sharing is done by multiplexing the pad input/output signals.

Every module requires a specific pad setting (such as pull up, keeper, and so on). The pad settings parameters are controlled by the IOMUXC.

The IOMUX consists only of combinatorial logic combined from several basic iomux cells. Each basic iomux cell handles only one pad signal's muxing.

NOTE

IOMUX registers control the PAD settings. To see the PAD mapping on this device with the PORT pins, refer to GPIO Mapping

NOTE

For TCON[x] signals, like tcon0 refer to DCU0_TCONx signal and tcon1 refer to DCU1_TCONx signal in the Pinouts table.

5.2 Memory map and register definition

IOMUXC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4004_8000	Software MUX Pad Control Register 0 (IOMUXC_PTA6)	32	R/W	0000_0060h	5.2.1/152

IOMUXC_PTB22 field descriptions

Field	Description
31–23 Reserved	This field is reserved.
22–20 MUX_MODE	MUX Mode Select Field. Select 1 of 3 IOMUX modes to be used for pad: PTB22. **NOTE:** Pad PTB22 is involved in Daisy Chain. • Config Register IOMUXC_VIDEO_IN0_IPP_IND_FID_SELECT_INPUT for mode ALT5. 000 Select mux mode: ALT0 mux port: GPIO[44] of instance: rgpioc. 001 Select mux mode: ALT1 mux port: SCK of instance: dspi0. 101 Select mux mode: ALT5 mux port: VIU_FID of instance: video_in0.
19–14 Reserved	This field is reserved.
13–12 SPEED	Speed Field. Select one of the following values for pad: PTB22. 00 Low (50 MHz) 01 Medium (100 MHz) 10 Medium (100 MHz) 11 High (200 MHz)

Table continues on the next page...

IOMUXC_PTB22 field descriptions (continued)

Field	Description
11 SRE	Slew Rate Field. Select one of the following values for pad: PTB22. 0 Slow Slew Rate 1 Fast Slew Rate
10 ODE	Open Drain Enable Field. Select one of the following values for pad: PTB22. 0 Output is CMOS 1 Output is open drain
9 HYS	Hysteresis Enable Field. Select one of the following values for pad: PTB22. 0 CMOS input 1 Schmitt trigger input
8–6 DSE	Drive Strength Field. Select one of the following values for pad: PTB22. 000 output driver disabled; 001 150 Ohm (240 Ohm if pad is DDR) 010 75 Ohm (120 Ohm if pad is DDR) 011 50 Ohm (80 Ohm if pad is DDR) 100 37 Ohm (60 Ohm if pad is DDR) 101 30 Ohm (48 Ohm if pad is DDR) 110 25 Ohm 111 20 Ohm (34 Ohm if pad is DDR)
5–4 PUS	Pull Up / Down Config Field. Select one of the following values for pad: PTB22. 00 100 kOhm Pull Down 01 47 kOhm Pull Up 10 100 kOhm Pull Up 11 22 kOhm Pull Up
3 PKE	Pull / Keep Enable Field. Select one of the following values for pad: PTB22. 0 Pull/Keeper Disabled 1 Pull/Keeper Enabled
2 PUE	Pull / Keep Select Field. Select one of the following values for pad: PTB22. 0 Keeper enable 1 Pull enable
1 OBE	Output Buffer Enable Field. Select one of the following values for pad: PTB22. 0 Disabled 1 Enabled
0 IBE	Input Buffer Enable Field. Select one of the following values for pad: PTB22. 0 Disabled 1 Enabled

IOMUXC_PTE12 field descriptions

Field	Description
31–23 Reserved	This field is reserved.
22–20 MUX_MODE	MUX Mode Select Field. Select 1 of 6 IOMUX modes to be used for pad: PTE12. 000 Select mux mode: ALT0 mux port: GPIO[117] of instance: rgpioc. 001 Select mux mode: ALT1 mux port: DATA_OUT[25] of instance: tcon0. 010 Select mux mode: ALT2 mux port: CS3 of instance: dspi1. 011 Select mux mode: ALT3 mux port: RCON5 of instance: src. 100 Select mux mode: ALT4 mux port: LCD12 of instance: lcd_64f6b. 111 Select mux mode: ALT7 mux port: LP_IN of instance: lptimer.
19–14 Reserved	This field is reserved.
13–12 SPEED	Speed Field. Select one of the following values for pad: PTE12. 00 Low (50 MHz) 01 Medium (100 MHz) 10 Medium (100 MHz) 11 High (200 MHz)

Table continues on the next page...

IOMUXC_PTE12 field descriptions (continued)

Field	Description
11 SRE	Slew Rate Field. Select one of the following values for pad: PTE12. 0 Slow Slew Rate 1 Fast Slew Rate
10 ODE	Open Drain Enable Field. Select one of the following values for pad: PTE12. 0 Output is CMOS 1 Output is open drain
9 HYS	Hysteresis Enable Field. Select one of the following values for pad: PTE12. 0 CMOS input 1 Schmitt trigger input
8–6 DSE	Drive Strength Field. Select one of the following values for pad: PTE12. 000 output driver disabled; 001 150 Ohm (240 Ohm if pad is DDR) 010 75 Ohm (120 Ohm if pad is DDR) 011 50 Ohm (80 Ohm if pad is DDR) 100 37 Ohm (60 Ohm if pad is DDR) 101 30 Ohm (48 Ohm if pad is DDR) 110 25 Ohm 111 20 Ohm (34 Ohm if pad is DDR)
5–4 PUS	Pull Up / Down Config Field. Select one of the following values for pad: PTE12. 00 100 kOhm Pull Down 01 47 kOhm Pull Up 10 100 kOhm Pull Up 11 22 kOhm Pull Up
3 PKE	Pull / Keep Enable Field. Select one of the following values for pad: PTE12. 0 Pull/Keeper Disabled 1 Pull/Keeper Enabled
2 PUE	Pull / Keep Select Field. Select one of the following values for pad: PTE12. 0 Keeper enable 1 Pull enable
1 OBE	Output Buffer Enable Field. Select one of the following values for pad: PTE12. 0 Disabled 1 Enabled
0 IBE	Input Buffer Enable Field. Select one of the following values for pad: PTE12. 0 Disabled 1 Enabled

5.2.119 Software MUX Pad Control Register 118 (IOMUXC_PTE13)

IOMUXC_PTE27 field descriptions (continued)

Field	Description
	0 Slow Slew Rate 1 Fast Slew Rate
10 ODE	Open Drain Enable Field. Select one of the following values for pad: PTE27. 0 Output is CMOS 1 Output is open drain
9 HYS	Hysteresis Enable Field. Select one of the following values for pad: PTE27. 0 CMOS input 1 Schmitt trigger input
8–6 DSE	Drive Strength Field. Select one of the following values for pad: PTE27. 000 output driver disabled; 001 150 Ohm (240 Ohm if pad is DDR) 010 75 Ohm (120 Ohm if pad is DDR) 011 50 Ohm (80 Ohm if pad is DDR) 100 37 Ohm (60 Ohm if pad is DDR) 101 30 Ohm (48 Ohm if pad is DDR) 110 25 Ohm 111 20 Ohm (34 Ohm if pad is DDR)
5–4 PUS	Pull Up / Down Config Field. Select one of the following values for pad: PTE27. 00 100 kOhm Pull Down 01 47 kOhm Pull Up 10 100 kOhm Pull Up 11 22 kOhm Pull Up
3 PKE	Pull / Keep Enable Field. Select one of the following values for pad: PTE27. 0 Pull/Keeper Disabled 1 Pull/Keeper Enabled
2 PUE	Pull / Keep Select Field. Select one of the following values for pad: PTE27. 0 Keeper enable 1 Pull enable
1 OBE	Output Buffer Enable Field. Select one of the following values for pad: PTE27. 0 Disabled 1 Enabled
0 IBE	Input Buffer Enable Field. Select one of the following values for pad: PTE27. 0 Disabled 1 Enabled

5.2.134 Software MUX Pad Control Register 133 (IOMUXC_PTE28)

Address: 4004_8000h base + 214h offset = 4004_8214h

IOMUXC_PTE28 field descriptions

Field	Description
31–23 Reserved	This field is reserved.
22–20 MUX_MODE	MUX Mode Select Field. Select 1 of 6 IOMUX modes to be used for pad: PTE28. **NOTE:** Pad PTE28 is involved in Daisy Chain. • Config Register IOMUXC_I2C1_IPP_SDA_IND_SELECT_INPUT for mode ALT5. 000 Select mux mode: ALT0 mux port: GPIO[133] of instance: rgpioc. 001 Select mux mode: ALT1 mux port: DATA_OUT[9] of instance: tcon0. 011 Select mux mode: ALT3 mux port: RCON17 of instance: src. 100 Select mux mode: ALT4 mux port: LCD28 of instance: lcd_64f6b. 101 Select mux mode: ALT5 mux port: SDA of instance: i2c1. 111 Select mux mode: ALT7 mux port: out of instance: ewm.
19–14 Reserved	This field is reserved.
13–12 SPEED	Speed Field. Select one of the following values for pad: PTE28. 00 Low (50 MHz) 01 Medium (100 MHz) 10 Medium (100 MHz) 11 High (200 MHz)
11 SRE	Slew Rate Field. Select one of the following values for pad: PTE28. 0 Slow Slew Rate 1 Fast Slew Rate
10 ODE	Open Drain Enable Field. Select one of the following values for pad: PTE28. 0 Output is CMOS 1 Output is open drain
9 HYS	Hysteresis Enable Field. Select one of the following values for pad: PTE28. 0 CMOS input 1 Schmitt trigger input
8–6 DSE	Drive Strength Field. Select one of the following values for pad: PTE28.

Table continues on the next page...

IOMUXC_PTE28 field descriptions (continued)

Field	Description
	000 output driver disabled; 001 150 Ohm (240 Ohm if pad is DDR) 010 75 Ohm (120 Ohm if pad is DDR) 011 50 Ohm (80 Ohm if pad is DDR) 100 37 Ohm (60 Ohm if pad is DDR) 101 30 Ohm (48 Ohm if pad is DDR) 110 25 Ohm 111 20 Ohm (34 Ohm if pad is DDR)
5–4 PUS	Pull Up / Down Config Field. Select one of the following values for pad: PTE28. 00 100 kOhm Pull Down 01 47 kOhm Pull Up 10 100 kOhm Pull Up 11 22 kOhm Pull Up
3 PKE	Pull / Keep Enable Field. Select one of the following values for pad: PTE28. 0 Pull/Keeper Disabled 1 Pull/Keeper Enabled
2 PUE	Pull / Keep Select Field. Select one of the following values for pad: PTE28. 0 Keeper enable 1 Pull enable
1 OBE	Output Buffer Enable Field. Select one of the following values for pad: PTE28. 0 Disabled 1 Enabled
0 IBE	Input Buffer Enable Field. Select one of the following values for pad: PTE28. 0 Disabled 1 Enabled

5.2.135 Software MUX Pad Control Register 134 (IOMUXC_PTA7)

Address: 4004_8000h base + 218h offset = 4004_8218h

5.3 Functional Description

The figure below shows the GPIO Pad .

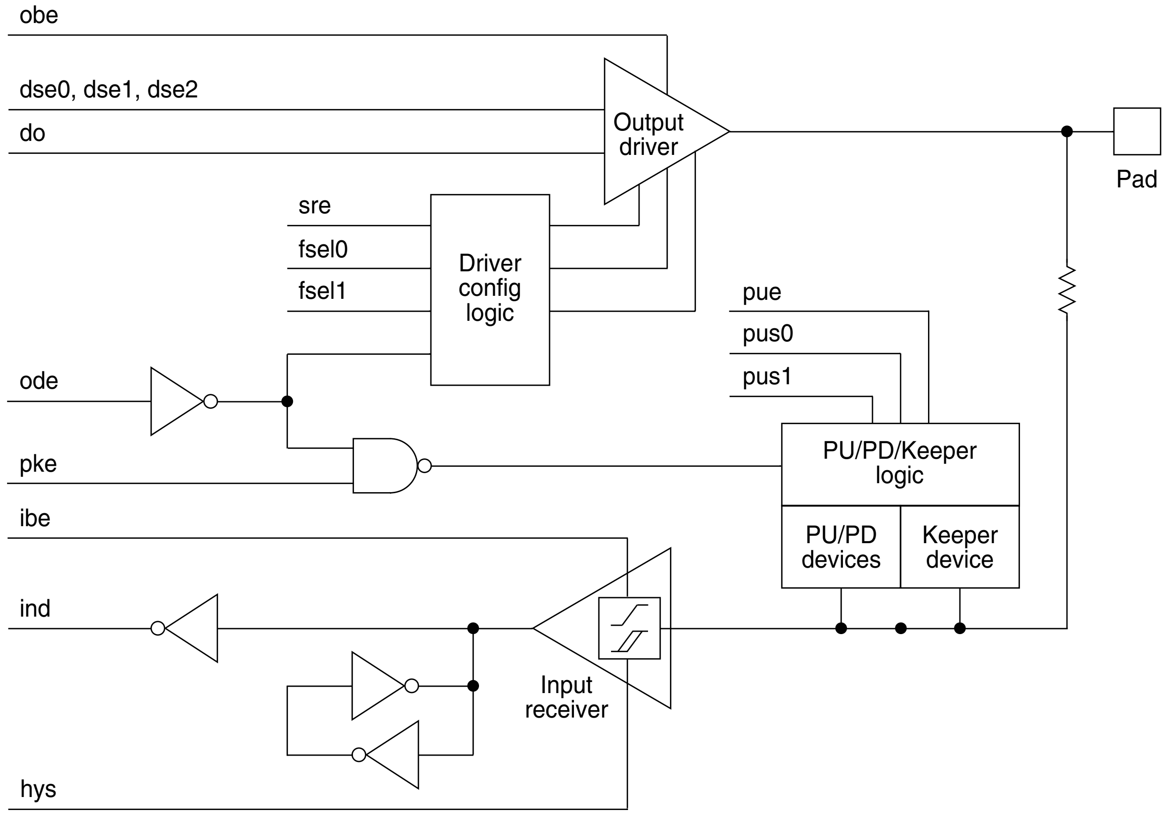

Figure 5-235. GPIO PAD

Table 5-236. Signal Description

Signal Name	Description	Description
Pad	Input/Output	I/O to external world
do	Input	Data coming from the core into the pad
obe	Input	Output enable
ode	Input	Select open drain or CMOS output
dse	Input	Drive Strength select
sre	Input	Slew rate of output buffer
fsel1, fsel0	Input	Slew rate control
pke	Input	Enable pull up, pull down and keeper capability
pue	Input	Enable pull-up/down or keeper
pus	Input	Pull-up/down select
ibe	Input	Input enable
ind	Output	Data coming out of the pad into the core
hys	Input	Select Schmitt trigger or CMOS input

NOTE

For DDR pads, there are additional control signals as explained in IOMUX register map to control DDR functionality.

Table 5-237. Truth Table

ode	obe	pke	pue	pus	do	dse	pad
Output Buffer Mode (functional)							
0	1	0	X	X	do	001, 010, 011, 100, 101, 110, 111	do
0	1	0	X	X	do	0	Z
0	0	0	X	X	X	X	Z
Output Buffer Mode + Keeper							
0	0	1	0	X	X	X	pad (keep previous state)
Output Buffer Mode + pull-up/pull-down resistors							
0	0	1	1	0	X	X	weak0 (pull-down 100 KOhm)
0	0	1	1	1	X	X	weak1 (pull-up 47 KOhm)
0	0	1	1	10	X	X	weak1 (pull-up 100 KOhm)
0	0	1	1	11	X	X	weak1 (pull-up 22 KOhm)
Open Drain Mode							
1	1	0	X	X	do	001, 010, 011, 100, 101, 110, 111	do
0	1	0	X	X	do	0	Z
1	0	0	X	X	X	X	Z
Open Drain Mode + Keeper/Pull-down							
1	1	1	0	X	0	X	0 (open drain + keeper)
1	1	1	0	X	1	X	weak0 (keeper)
1	1	1	1	0	1	X	0 (open drain + pull-down)
Open Drain Mode + Pull-up							
1	1	1	1	1	0	X	0 (open drain + pull-up 47 KOhm)
1	1	1	1	10	0	X	0 (open drain + pull-up 100 KOhm)

Table continues on the next page...

Table 5-237. Truth Table (continued)

ode	obe	pke	pue	pus	do	dse	pad
1	1	1	1	11	0	X	0 (open drain + pull-up 22 KOhm)
1	1	1	1	1	1	X	weak1 (open drain +pull-up 47 KOhm)
1	1	1	1	10	1	X	weak1 (open drain +pull-up 100 KOhm)

1	0	0	X	X	X	X	Z
1	0	1	0	X	X	X	pad (keep previous state)

Table 5-238. Truth Table - Pad to Core

ibe	pad	ind (keep previous state)
0	X	ind
1	pad	pad

IOMUX module is used to configure the Pad settings through the IOMUX registers and multiplex multiple modules on to a single PAD and drive input to a module from multiple PADs. Muxing is done only on obe, ibe, ind and do and rest of the pad settings are through IOMUX registers. DDR pads are dedicated pads for DDR and there is no muxing on them.

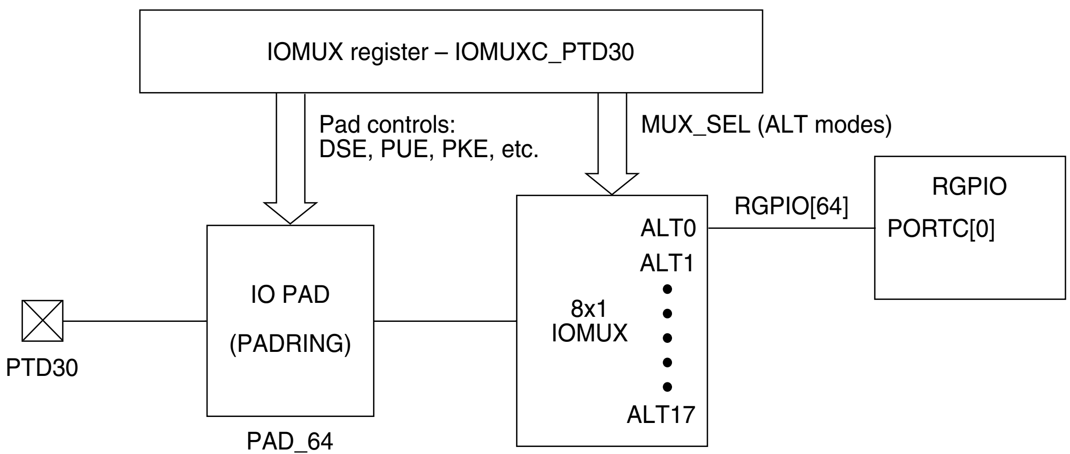

Figure 5-236. Path from the pint PTD30 to RGPIO

5.4 Special Pad Settings

This section describes the special pad setting requirements for several modules in this device. DDR Pins are dedicated pins and do not have any alternate functionality on them. The settings of DDR Pins are controlled by IOMUX as well as DDR module. GPIO Pin settings (speed, sre, ode, hys, dse, pus, pke,pue) are controlled by IOMUX registers, however, special care needs to be taken for ibe/obe. The input buffer of the Pin is enabled by ibe bit in IOMUX register. The output buffer of the Pin is enabled by obe bit of IOMUX only if ALT Mode is configured as GPIO. In other ALT modes, the module configured for ALT mode drives the obe signal to output buffer of Pin and obe bit of IOMUX will have no effect. This is done to reduce the propagation delay it takes for module to enable ibe and data from pin to reach module. This helps to ease timing requirements for modules which enable/disable input buffer dynamically.

5.4.1 DUMMY PADS (DDR/QuadSPI)

There are two dummy pads that are useful for timing calibration of DDR. These pads are internal only, but there corresponding IOMUX register need to be programmed for correct operation of DDR. These registers are:

- IOMUXC_DUMMY_DDRBYTE1 (0x400482DC)
- IOMUXC_DUMMY_DDRBYTE2 (0x400482E0)

DDR: Dummy pads for DDR must be configured before any DDR I/O transactions are done. These pads simulate the input delay of the I/O buffers from the DRAM devices and DDR configures the delays accordingly.

QuadSPI: Dummy pads for QuadSPI can be used to loopback clock while interfacing with devices that do not provide external DQS.

5.4.2 SDHC

Although SDHC_DCLK is output-only signal, ibe needs to be enabled as the module requires output clock to be looped-back through the pad’s input buffer to ease timing requirements.

5.4.3 I2C

I2C pins, SCL and SDA are both Open-drain and bi-directional. Hence, ODE bit should be set in IOMUX registers and ibe enabled.

5.4.4 FlexBus

Flexbus module provides CSPMCR register for additional muxing apart from IOMUX. These registers may need to be programmed depending on the use-case desired.

5.4.5 LCD/ADC

When a pad is configured for LCD or ADC by programming appropriate ALT_MODE, ensure that both ibe/obe of the pad are disabled and all pulls/keeper are disabled as well. This is because input and output buffer are for digital inputs and analog signals from/to LCD/ADC are connected through a resistor directly to pad. If ibe/obe/pke are set, then there will be leakage and potential performance degradation.

5.4.6 SCI

Pull-ups should be enabled to ensure there are no spurious transitions.

5.4.7 Reset Pin Configuration

The configuration of Reset Pin cannot be changed and is not controllable through IOMUX. Its configuration is fixed as follows:

- Speed: 100 Mhz
- Slew Rate: Slow
- Open Drain: Disable (Output is CMOS)
- Hysteresis: Disable (CMOS input)
- Drive Strength: 25 Ohm
- Pull Up/Down: 100KOhm Pull-UP
- Pull/Keep Enable: Enable
- Pull/Keep Select: Pull Selected
- ibe/obe/do/ind: Controlled through Reset Controller

5.4.8 Typical IOMUX Configuration

The table below shows the typical IOMUX configuration of pads for different modules on this device. This is sample configuration only and will change based on the instance of the module and pads involved.

Table 5-239. Typical IOMUX Configuration

Module Name	Signal Name	Direction	SPEED	HYS	ODE	PUE	SRE	DSE	PUS	PKE	IBE

Chapter 6
Port control and interrupts (PORT)

6.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

6.2 Overview

The port control and interrupt (PORT) module provides support for digital filtering, and external interrupt functions. Most functions can be configured independently for each pin in the 32-bit port and affect the pin regardless of its pin muxing state.

There is one instance of the PORT module for each port. Not all pins within each port are implemented on a specific device.

6.2.1 Features

The PORT module has the following features:

- Pin interrupt
  - Interrupt flag and enable registers for each pin
  - Support for edge sensitive (rising, falling, both) or level sensitive (low, high) configured per pin
  - Support for interrupt or DMA request configured per pin
  - Asynchronous wakeup in Low-Power modes
  - Pin interrupt is functional in all digital Pin Muxing modes
- Digital input filter

- Digital input filter for each pin, usable by any digital peripheral muxed onto the pin
- Individual enable or bypass control field per pin
- Selectable clock source for digital input filter with a five bit resolution on filter size
- Functional in all digital Pin Muxing modes

6.2.2 Modes of operation

6.2.2.1 Run mode

In Run mode, the PORT operates normally.

6.2.2.2 Wait mode

In Wait mode, PORT continues to operate normally and may be configured to exit the Low-Power mode if an enabled interrupt is detected. DMA requests are still generated during the Wait mode, but do not cause an exit from the Low-Power mode.

6.2.2.3 Stop mode

In Stop mode, the PORT can be configured to exit the Low-Power mode via an asynchronous wakeup signal if an enabled interrupt is detected.

In Stop mode, the digital input filters are bypassed unless they are configured to run from the 1 kHz LPO clock source.

6.2.2.4 Debug mode

In Debug mode, PORT operates normally.

6.3 External signal description

The following table describes the PORT external signal.

Table 6-1. Signal properties

Name	Function	I/O	Reset	Pull
PORTx[31:0]	External interrupt	I/O	0	-

NOTE

Not all pins within each port are implemented on each device.

6.4 Detailed signal description

The following table contains the detailed signal description for the PORT interface.

Table 6-2. PORT interface—detailed signal description

Signal	I/O	Description	
PORTx[31:0]	I/O	External interrupt.	
		State meaning	Asserted—pin is logic one. Negated—pin is logic zero.
		Timing	Assertion—may occur at any time and can assert asynchronously to the system clock. Negation—may occur at any time and can assert asynchronously to the system clock.

6.5 Memory map and register definition

Any read or write access to the PORT memory space that is outside the valid memory map results in a bus error. All register accesses complete with zero wait states.

PORT memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4004_9000	Pin Control Register n (PORT0_PCR0)	32	R/W	0000_0000h	6.5.1/525

6.5.1 Pin Control Register n (PORTx_PCRn)

NOTE

Refer to the Signal Multiplexing and Pin Assignment chapter for the reset value of this device.

See the GPIO Configuration section for details on the available functions for each pin.

Do not modify pin configuration registers associated with pins not available in your selected package. All un-bonded pins not available in your package will default to DISABLE state for lowest power consumption.

Address: Base address + 0h offset + (4d × i), where i=0d to 31d

PORTx_PCRn field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 ISF	Interrupt Status Flag The pin interrupt configuration is valid in all digital pin muxing modes. 0 Configured interrupt is not detected. 1 Configured interrupt is detected. If the pin is configured to generate a DMA request, then the corresponding flag will be cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic one is written to the flag. If the pin is configured for a level sensitive interrupt and the pin remains asserted, then the flag is set again immediately after it is cleared.
23–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–16 IRQC	Interrupt Configuration

Table continues on the next page...

PORTx_PCR*n* field descriptions (continued)

Field	Description
	The pin interrupt configuration is valid in all digital pin muxing modes. The corresponding pin is configured to generate interrupt/DMA request as follows: 0000 Interrupt/DMA request disabled. 0001 DMA request on rising edge. 0010 DMA request on falling edge. 0011 DMA request on either edge. 1000 Interrupt when logic zero. 1001 Interrupt on rising edge. 1010 Interrupt on falling edge. 1011 Interrupt on either edge. 1100 Interrupt when logic one. Others Reserved.
15–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

6.5.2 Interrupt Status Flag Register (PORTx_ISFR)

The pin interrupt configuration is valid in all digital pin muxing modes. The Interrupt Status Flag for each pin is also visible in the corresponding Pin Control Register, and each flag can be cleared in either location.

Address: Base address + A0h offset

Bit	31–0
R	ISF
W	w1c
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

PORTx_ISFR field descriptions

Field	Description
31–0 ISF	Interrupt Status Flag Each bit in the field indicates the detection of the configured interrupt of the same number as the field. 0 Configured interrupt is not detected. 1 Configured interrupt is detected. If the pin is configured to generate a DMA request, then the corresponding flag will be cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic one is written to the flag. If the pin is configured for a level sensitive interrupt and the pin remains asserted, then the flag is set again immediately after it is cleared.

6.5.3 Digital Filter Enable Register (PORTx_DFER)

The digital filter configuration is valid in all digital pin muxing modes.

Address: Base address + C0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PORTx_DFWR field descriptions

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–0 FILT	Filter Length The digital filter configuration is valid in all digital pin muxing modes. Configures the maximum size of the glitches, in clock cycles, that the digital filter absorbs for the enabled digital filters. Glitches that are longer than this register setting will pass through the digital filter, and glitches that are equal to or less than this register setting are filtered. Changing the filter length must be done only after all filters are disabled.

6.6 Functional description

6.6.1 External interrupts

The external interrupt capability of the PORT module is available in all digital pin muxing modes provided the PORT module is enabled.

Each pin can be individually configured for any of the following external interrupt modes:

- Interrupt disabled, default out of reset
- Active high level sensitive interrupt

- Active low level sensitive interrupt
- Rising edge sensitive interrupt
- Falling edge sensitive interrupt
- Rising and falling edge sensitive interrupt
- Rising edge sensitive DMA request
- Falling edge sensitive DMA request
- Rising and falling edge sensitive DMA request

The interrupt status flag is set when the configured edge or level is detected on the pin or at the output of the digital input filter, if the digital input digital filter is enabled. When not in Stop mode, the input is first synchronized to the bus clock to detect the configured level or edge transition.

The PORT module generates a single interrupt that asserts when the interrupt status flag is set for any enabled interrupt for that port. The interrupt negates after the interrupt status flags for all enabled interrupts have been cleared by writing a logic 1 to the ISF flag in either the PORT_ISFR or PORT_PCRn registers.

The PORT module generates a single DMA request that asserts when the interrupt status flag is set for any enabled DMA request in that port. The DMA request negates after the DMA transfer is completed, because that clears the interrupt status flags for all enabled DMA requests.

During Stop mode, the interrupt status flag for any enabled interrupt is asynchronously set if the required level or edge is detected. This also generates an asynchronous wakeup signal to exit the Low-Power mode.

6.6.2 Digital filter

The digital filter capabilities of the PORT module are available in all digital Pin Muxing modes if the PORT module is enabled.

The clock used for all digital filters within one port can be configured between the bus clock or the 1 kHz LPO clock. This selection must be changed only when all digital filters for that port are disabled. If the digital filters for a port are configured to use the bus clock, then the digital filters are bypassed for the duration of Stop mode. While the digital filters are bypassed, the output of each digital filter always equals the input pin, but the internal state of the digital filters remains static and does not update due to any change on the input pin.

The filter width in clock size is the same for all enabled digital filters within one port and must be changed only when all digital filters for that port are disabled.

The output of each digital filter is logic zero after system reset and whenever a digital filter is disabled. After a digital filter is enabled, the input is synchronized to the filter clock, either the bus clock or the 1 kHz LPO clock. If the synchronized input and the output of the digital filter remain different for a number of filter clock cycles equal to the filter width register configuration, then the output of the digital filter updates to equal the synchronized filter input.

The minimum latency through a digital filter equals two or three filter clock cycles plus the filter width configuration register.

Chapter 7
General-Purpose Input/Output (GPIO)

7.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The general-purpose input and output (GPIO) module communicates to the processor core via a zero wait state interface (IOPORT) for maximum pin performance. The GPIO registers support 8-bit, 16-bit or 32-bit accesses.

The GPIO data direction and output data registers control the direction and output data of each pin when the pin is configured for the GPIO function. The GPIO input data register displays the logic value on each pin when the pin is configured for any digital function, provided the corresponding Port Control and Interrupt module for that pin is enabled.

Efficient bit manipulation of the general-purpose outputs is supported through the addition of set, clear, and toggle write-only registers for each port output data register.

7.1.1 Features

- Features of the GPIO module include:
  - Pin input data register visible in all digital pin-multiplexing modes
  - Pin output data register with corresponding set/clear/toggle registers
  - Zero wait state access to GPIO registers through IOPORT

NOTE

GPIO module is clocked by system clock.

7.1.2 Modes of operation

The following table depicts different modes of operation and the behavior of the GPIO module in these modes.

Table 7-1. Modes of operation

Modes of operation	Description
Run	The GPIO module operates normally.
Wait	The GPIO module operates normally.
Stop	The GPIO module is disabled.
Debug	The GPIO module operates normally.

7.1.3 GPIO signal descriptions

Table 7-2. GPIO signal descriptions

GPIO signal descriptions	Description	I/O
PORT0[31:0]	General-purpose input/output	I/O
PORT1[31:0]	General-purpose input/output	I/O
PORT2[31:0]	General-purpose input/output	I/O
PORT3[31:0]	General-purpose input/output	I/O
PORT4[31:0]	General-purpose input/output	I/O

NOTE

Not all pins within each port are implemented on each device. See the chapter on signal multiplexing for the number of GPIO ports available in the device.

7.1.3.1 Detailed signal description

Table 7-3. GPIO interface-detailed signal descriptions

Signal	I/O	Description	
PORT0[31:0] PORT1[31:0] PORT2[31:0] PORT3[31:0] PORT4[31:0]	I/O	General-purpose input/output	
		State meaning	Asserted: The pin is logic 1. Deasserted: The pin is logic 0.
		Timing	Assertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock. Deassertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock.

7.2 Memory map and register definition

Any read or write access to the GPIO memory space that is outside the valid memory map results in a bus error.

NOTE

For simplicity, each GPIO port's registers appear with the same width of 32 bits, corresponding to 32 pins. The actual number of pins per port (and therefore the number of usable control bits per port register) is chip-specific. Refer to the Chip Configuration chapter to see the exact control bits for the non-identical port instance.

GPIOx_PDIR field descriptions

Field	Description
31–0 PDI	Port Data Input Reads 0 at the unimplemented pins for a particular device. Pins that are not configured for a digital function read 0. If the Port Control and Interrupt module is disabled, then the corresponding bit in PDIR does not update. 0 Pin logic level is logic 0, or is not configured for use by digital function. 1 Pin logic level is logic 1.

7.3 Functional description

7.3.1 General-purpose input

The logic state of each pin is available via the Port Data Input registers, provided the pin is configured for a digital function and the corresponding Port Control and Interrupt module is enabled.

The Port Data Input registers return the synchronized pin state after any enabled digital filter in the Port Control and Interrupt module. The input pin synchronizers are shared with the Port Control and Interrupt module, so that if the corresponding Port Control and Interrupt module is disabled, then synchronizers are also disabled. This reduces power consumption when a port is not required for general-purpose input functionality.

Chapter 8
Chip Configuration

8.1 Introduction

This chapter provides details on the individual modules of the device. It includes:

- specific module-to-module interactions not necessarily discussed in the individual module chapters
- number of instances of the module in the device and their features
- number of instances of the module in the device and the differences in the features (if any)
- register differences between the multiple instances of a module

8.2 Core modules

8.2.1 Cortex-M4 Processor Core

Cortex-M4 implements the ARMv7-ME instruction set architecture (ISA): this is the Thumb2 definition - it provides compatibility with Cortex-M3 and adds significant new capabilities with DSP and SIMD extensions. The basic multiply-accumulate instructions support operations up to 32 x 32 + 64. Cortex-M4 also includes a single-precision floating-point unit (FPU), which includes an extension register file of thirty-two 32-bit floating-point data registers. Cortex-M4 complex includes the FPU and two 32-bit system bus interfaces. The device Cortex-M4 implementations include two tightly-coupled local memories and two cache memories connected to these bus interfaces although the device implementation connects to the 64-bit system bus interconnect and supports a 32-byte cache line size.

- L1 2-way set-associative 16kB Instruction cache with 32B line size length
- L1 2-way set-associative 16kB Data cache with 32B line size length

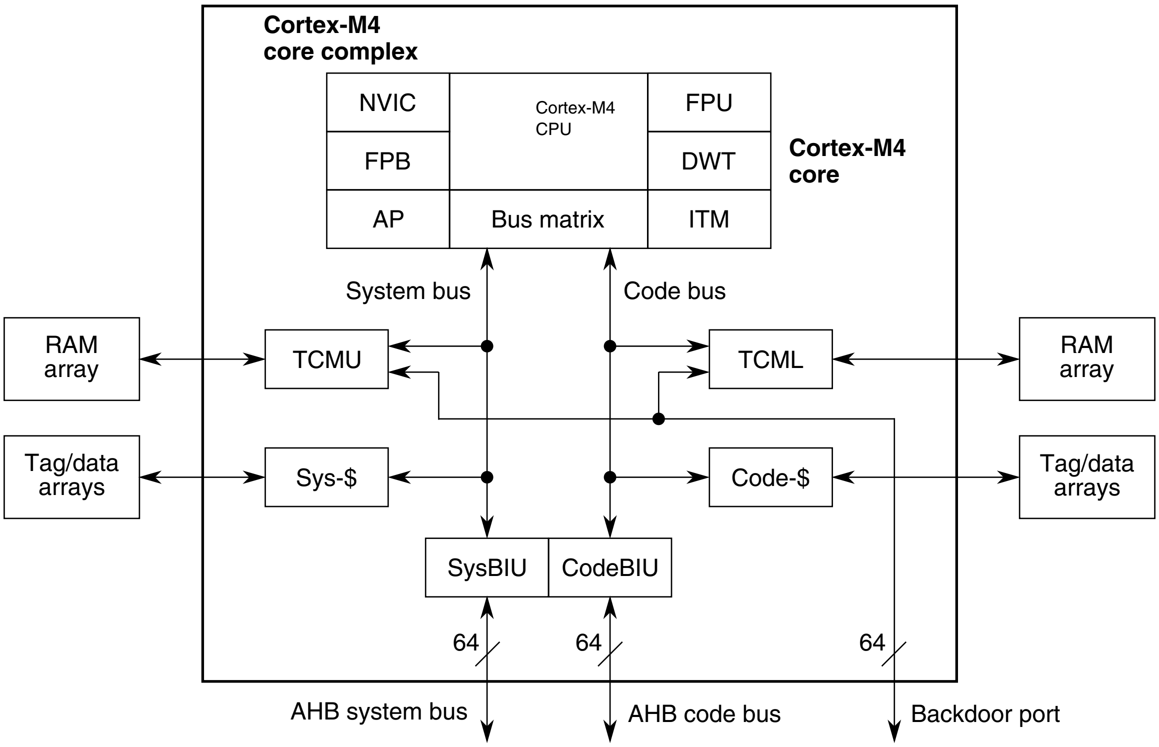

Figure 8-1. Cortex-M4 Block Diagram

Cortex-M4 core features a single issue, three stage pipeline microarchitecture. A high-level spatial pipeline block diagram of the CPU is shown below. The stages of the pipeline include:

- Fe - Instruction fetch stage where data is returned from instruction memory
- De - Instruction decode stage, generation of Load/Store Unit (LSU) address using forwarded register ports and immediate offset of LR register branch forwarding
- Ex - Instruction execute stage, single pipeline with multi-cycle stalls, LSU address/ data pipelining to AHB interface, multiply/divide and ALU with branch result

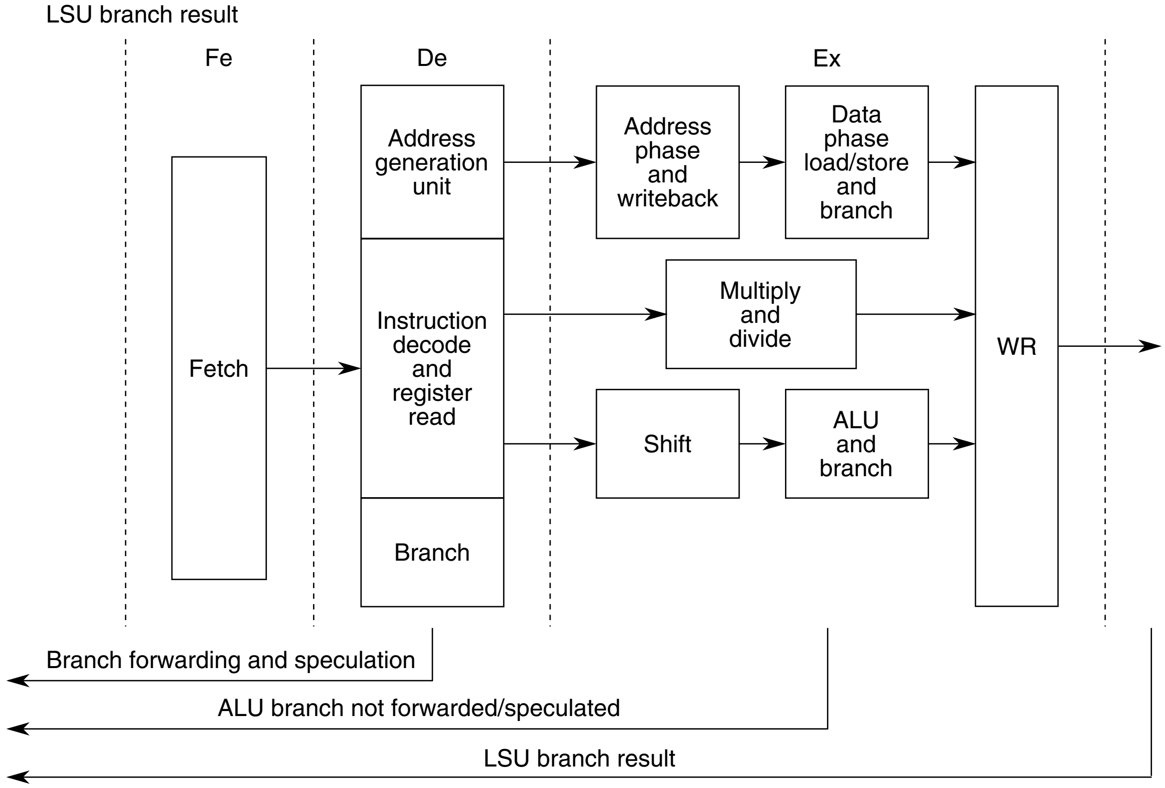

Figure 8-2. Cortex-M4 Pipeline Block Diagram

8.2.2 Cortex-M4 Instruction Fetches on the System Bus

The Cortex-M4 processors implement multiple 32-bit bus interfaces that support a Harvard memory architecture. Specifically, the cores provide a modified Harvard connection with 2-cycle pipelined AMBA-AHB code and system buses. The modified Harvard memory architecture results since the bus interfaces are activated by address range and include both instruction fetches and operand data references on a given bus port. A traditional Harvard architecture separates instruction fetches and operand data references onto specific bus ports regardless of access address.

The code bus is typically used for instruction fetching and data accesses of PC-relative data, while the system bus is typically used for operand data references to the on- and off-chip memories and peripheral accesses. This bus structure fully supports concurrent instruction fetch and data accesses, but the Cortex-M4 implementations can generate both types of references on each bus. Additionally, there is a separate 32-bit Private Peripheral Bus (PPB) connection to several important modules (for example, the Nested Vectored Interrupt Controller) accessible to only the core. By placing the various code and data sections in the appropriate locations within the memory map, overall system performance can be maximized.

To provide a “clean timing interface” on the core's system bus, instruction and vector fetch requests to this bus are registered. This increases fetch time by an additional cycle of latency because instructions fetched from the system bus take a minimum of two cycles. This also means that back-to-back instruction fetches from the system bus are not possible.

Instruction fetch requests to the code bus are not registered. It is recommended that performance critical code be located such that it fetches from the ICode bus interface as defined by addresses < 0x2000_0000 (the system bus interface includes the addresses > = 0x2000_0000 and < 0xE000_0000 and the Private Peripheral Bus is used for addresses >= 0xE000_0000).

NOTE

In the device, the memory map includes aliased address spaces that are mapped into the ICode region for code sections that reside in the system address space. As a simple example, the DDR address space is located in the system region of the memory map, but a subset of this space is aliased so that it appears in the ICode region that instructions mapped into the DDR space can be executed as maximum performance.

8.2.3 Cortex-A5 Processor Core

The Cortex-A5 processor is a high-performance, low-power ARM macrocell with an L1 cache subsystem that provides full virtual memory capabilities. The core supports the ARMv7-A instruction set architecture (supporting 32-bit ARM plus 16- and 32-bit Thumb{-2} instructions) and the microarchitecture has been optimized for area, performance/power efficiency, scalability and flexibility. It is architecturally compatible with the Cortex-A9.

It includes both an FPU and the NEON Media Processing Engine. The Cortex-A5 Floating Point Unit (FPU) is a VFPv4-D16 implementation of the ARM v7 floating-point architecture. The unit provides floating-point computation functionality that is compliant with the ANSI/IEEE Std 754-1985, IEEE Standard for Binary Floating-Point Arithmetic (IEEE 754).

The FPU includes all data processing instructions and data types in the VFPv4 architecture and fully supports single-precision and double-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions. The FPU is tightly integrated to the Cortex-A5 processor pipeline.

The NEON Media Processing Engine (MPE) extends the capabilities of the FPU with an implementation of the ARM NEON Advanced SIMD v2 instruction set for further acceleration of media and signal processing functions. It includes an additional register set supporting a rich set of SIMD operations over 8, 16, and 32-bit integer and 32-bit floating-point data types. The Cortex-A5 implements TrustZone® Technology to ensure reliable implementation of security applications ranging from digital rights management to electronic payment.

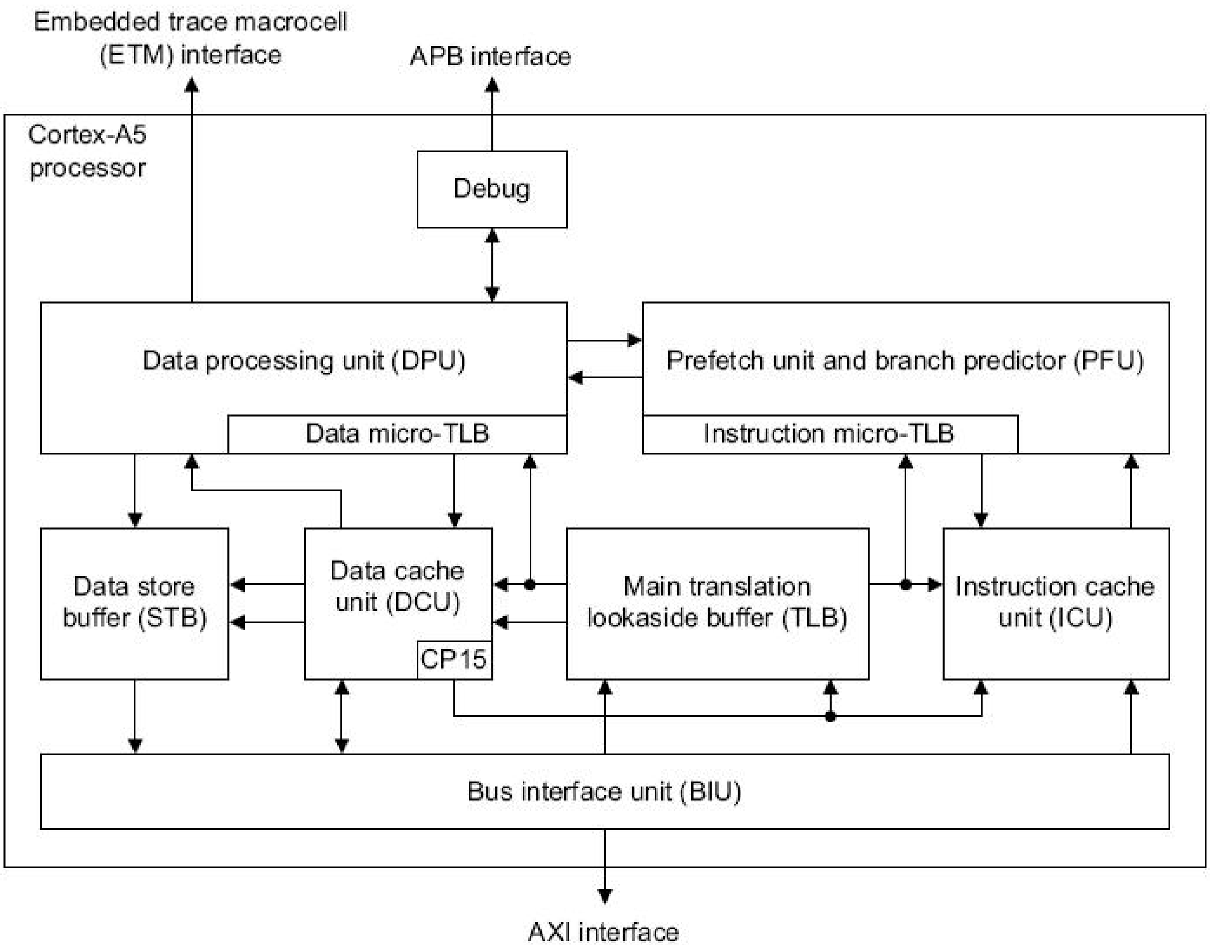

Figure 8-3. Cortex-A5 Processor Core Block Diagram

The processor microarchitecture implements a single issue, 8-stage pipeline design capable of 1.57 DMIPS per MHz performance. For the device, the configurable L1 caches are defined as 32K I- and 32K D-Caches and the system bus interface is a high performance 64-bit AXI bus that supports multiple outstanding transactions and has over 3x the memory bandwidth of the ARM1176JZ-S.

- L1 2-way set-associative 32 KB Instruction cache with 32B line size length
- L1 4-way set-associative 32 KB Data cache with 32B line size length
- L2 8-way set associative 512 KB cache with 32B line size length

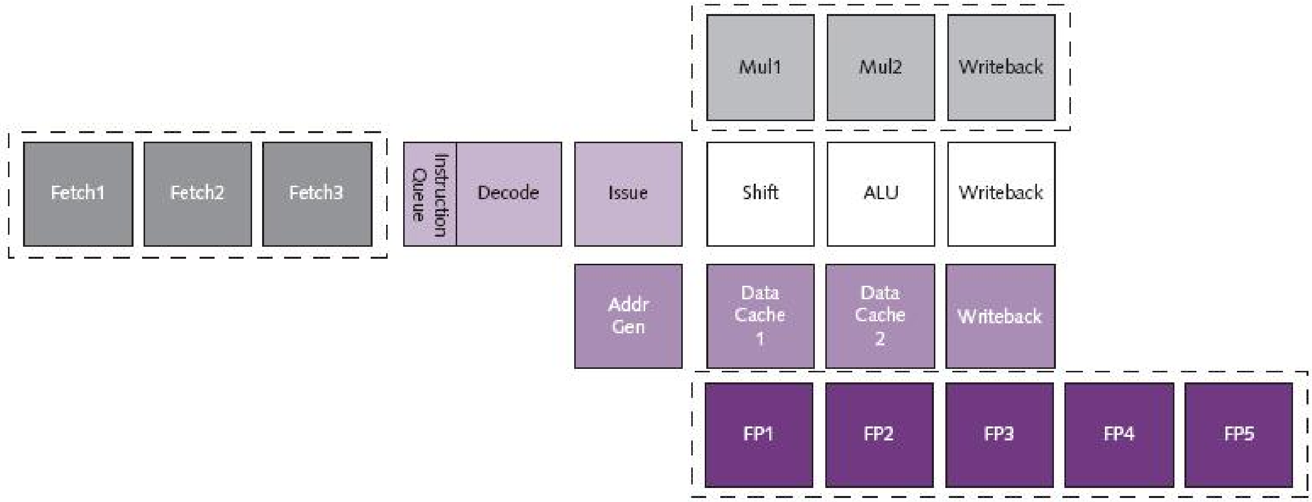

Figure 3. ARM Cortex-A5 pipelines. The basic integer pipeline is eight stages deep, including three prefetch stages that set up branch prediction. An instruction queue decouples the prefetch stages from the ALU section of the pipeline. A three-stage multiplier can execute 32- x 32-bit multiplies at a throughput rate of one instruction per cycle. Load/store instructions distribute the cache accesses over multiple stages to reduce critical timing paths. If the optional FPU or Neon extensions are present, a separate five-stage pipeline handles those operations.

Figure 8-4. Cortex-A5 Processor Pipeline Organization

NOTE

MII mode is supported for MAC0 only and when MII mode for MAC0 is enabled, RMII of MAC1 cannot be used.

8.2.4 Interrupt Assignments

Cortex-A5 uses the ARM Generic Interrupts Controller (GIC) architecture version 1.0.

Cortex-M4 uses the Nested Vectored Interrupt Controller (NVIC).

All peripheral interrupts on the device will be directed to a specific interrupt controller (GIC or NVIC) through an Interrupt Router module. In addition to the shared peripheral interrupts, there are CPU-to-CPU interrupts that will pass through the Interrupt Router. Finally, a small number of private peripheral interrupts to each core will connect directly to the NVIC or the GIC. For example, the L2 cache interrupts that are only relevant to the CortexA5 core. The GIC can support up to 16 Private Peripheral Interrupts (PPIs).

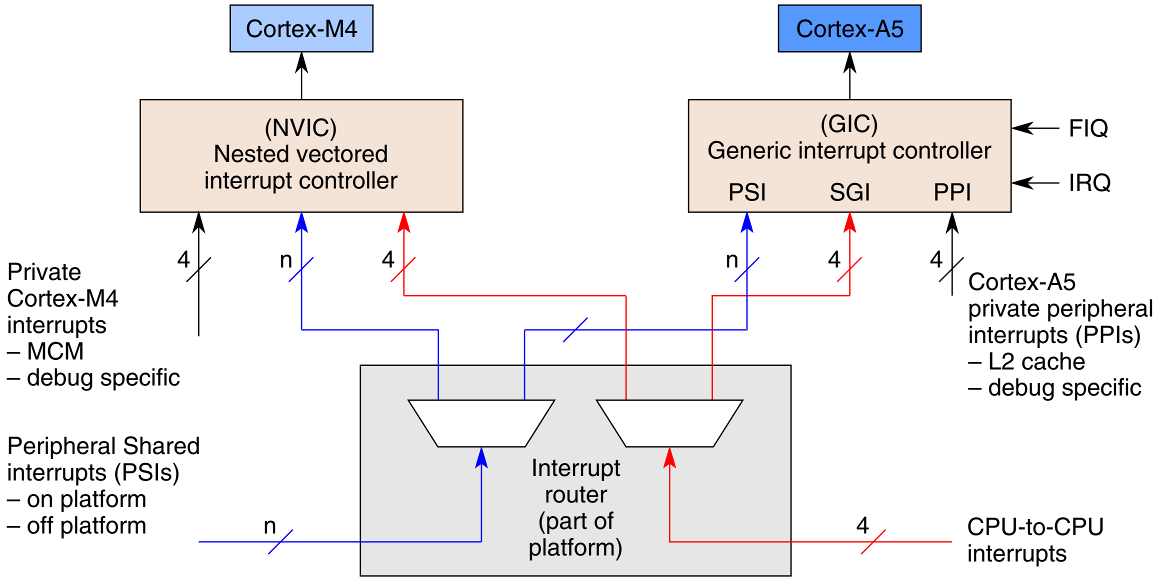
The following diagram shows the high level architecture of the device interrupts.



8.3 DMA MUX Request Sources

8.3.1 DMA MUX Request Sources

This device includes a DMA request mux that allows up to 64 DMA request signals to be mapped to any of the 16 DMA channels.The first four channels of DMA MUX provide periodic triggering capability.The trigger is generated by Periodic Interrupt Timer (PIT[3:0]).

Each DMA includes two DMA request MUXes that allows up to 126 DMA request signals. As shown in Figure below, request from MUX0 can be mapped to any of the first 16 DMA channels and from MUX1, to any of the upper 16 DMA channels. While for the second DMA, it is vice versa.

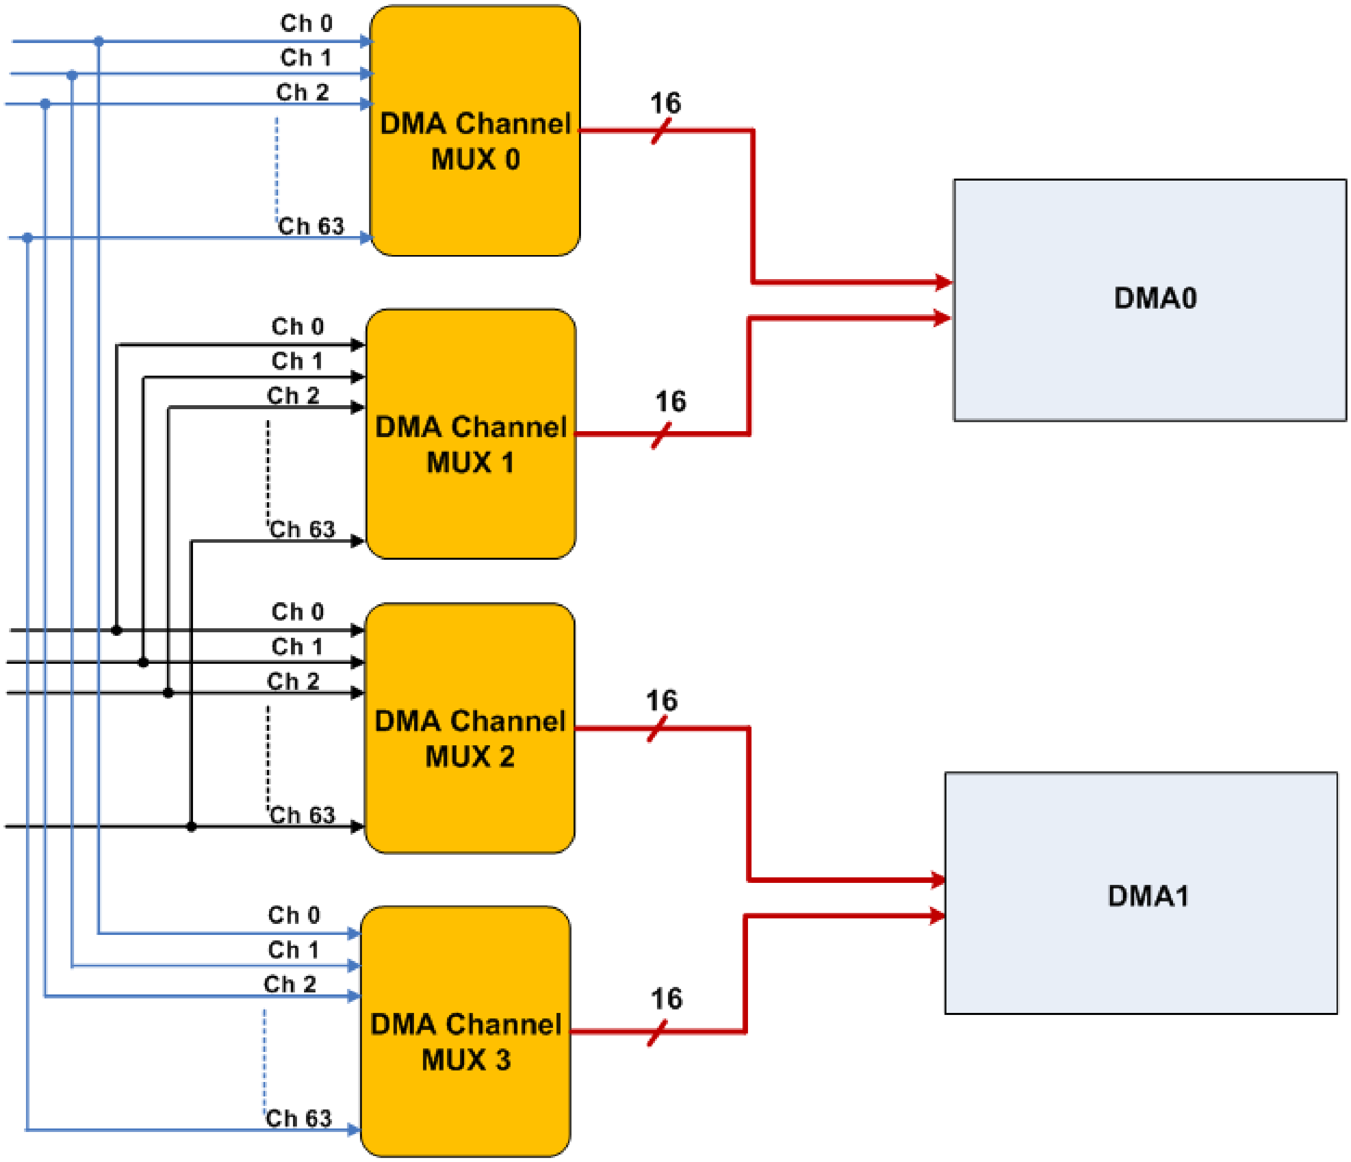


Figure 8-5. DMA Request MUX/DMA Structure

To allow for flexibility and optimal usage of the available DMA channels some of the DMA request sources are available on both muxes.

Because of the mux there is not a hard correlation between any of the DMA request sources and a specific DMA channel.

NOTE

Two duplicate Channel Mux cannot be enabled simultaneously for two (same) peripherals.

8.4 Wake-up Unit

8.4.1 WKPU configuration

The WKPU includes the following features.

- One NMI source
- 17 external interrupt sources with glitch filtering
- One external interrupt vector
- Five on-chip wakeup sources
- 12-bit address width
- 00000000b NMI default destination address

The table below shows the internal and external inputs to the WKUP module supported by the device.

Table 8-4. WKUP Pins

8.5 CMU Chip Signals

8.5.1 CMU Chip Signals

This table correlate the chip-level signal name with the signal name used in the module's chapter.

Table 8-5. CMU Signals Mapping

Chip Signal Name	Module Signal Name
Bus Clock	CLKMN1f
FXOSC	CLKMN0_RMT
FIRC	CLKMT0_RMN
SIRC	CLKMT1
Tied to 0	CLKMT2

8.6 Timers

8.6.1 FlexTimer

8.6.1.1 Instantiation Information

The following table shows how these modules are configured, including the number of channels supported.

Table 8-6. FTM Instantiations

	176 LQFP	364 BGA	Features/Usage
FTM0	8	8	3-phase motor + 2 general purpose or stepper motor
FTM1	2	2	Quadrature decoder or general purpose
FTM2	2	2	Quadrature decoder or general purpose
FTM3	0	8	3-phase motor + 2 general purpose or stepper motor

The FTM1 and FTM2 configuration differs from the FTM0 and FTM3 configuration by reduced number of channels and adding Quadrature decoder.

8.6.1.2 FTM Hardware Triggers

Following table provides the hardware trigger options for FTMs.

Table 8-7. FTM Hardware Trigger options

Hardware Triggers	FTM0	FTM1	FTM2	FTM3
Trigger 1	ADC0	ADC0	ADC0	ADC0
Trigger 2	ADC1	ADC1	ADC1 or USB1 SOF	ADC1 or USB1 SOF
Trigger 3	EXTRIG or USB0 SOF	EXTRIG or USB0 SOF	EXTRIG or USB0 SOF	EXTRIG or USB0 SOF

Each flextimer has 3 trigger inputs (0/1/2) which are configured using SRC MISC0 register.

The following figures show the flextimer triggers for each instance.

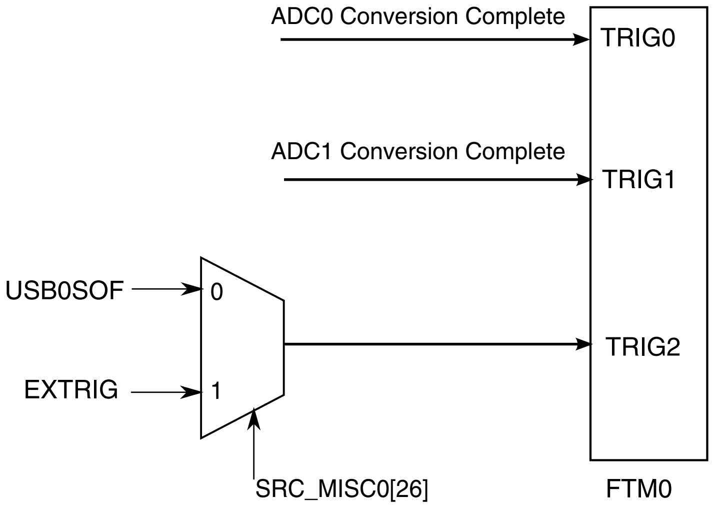

Figure 8-6. FTM0 Triggers

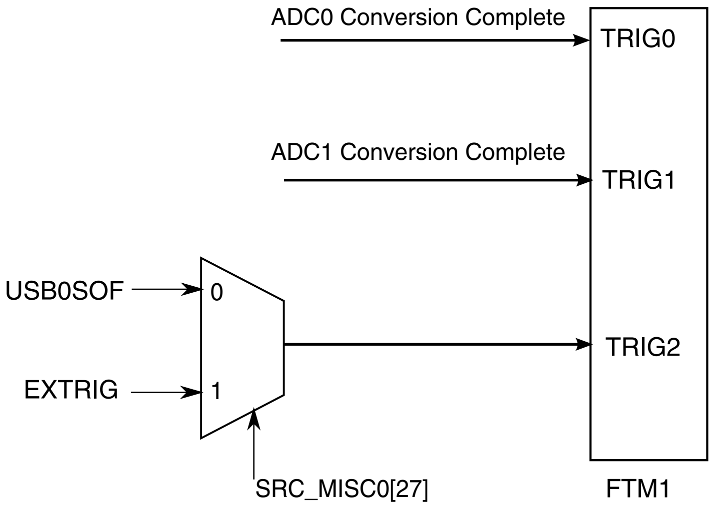

Figure 8-7. FTM1 Triggers

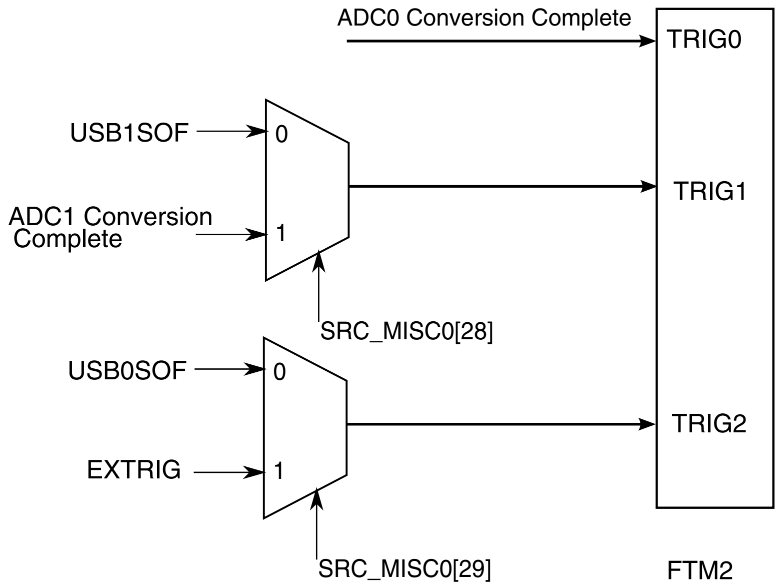

Figure 8-8. FTM2 Triggers

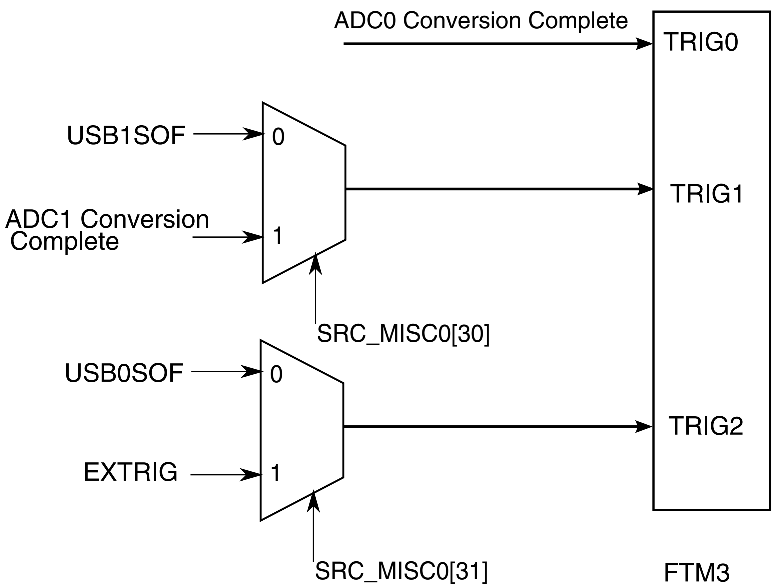

Figure 8-9. FTM3 Triggers

8.6.1.3 FTM output triggers for other modules

Following are the FTM Output Triggers options

- ADC0
- ADC1
- DAC0
- DAC1

8.6.1.4 FTM Global Time Base

This chip provides the optional FTM global time base feature (see Global time base (GTB)).

FTM0 provides the only source for the FTM global time base. The other FTM modules can share the time base as shown in the following figure:

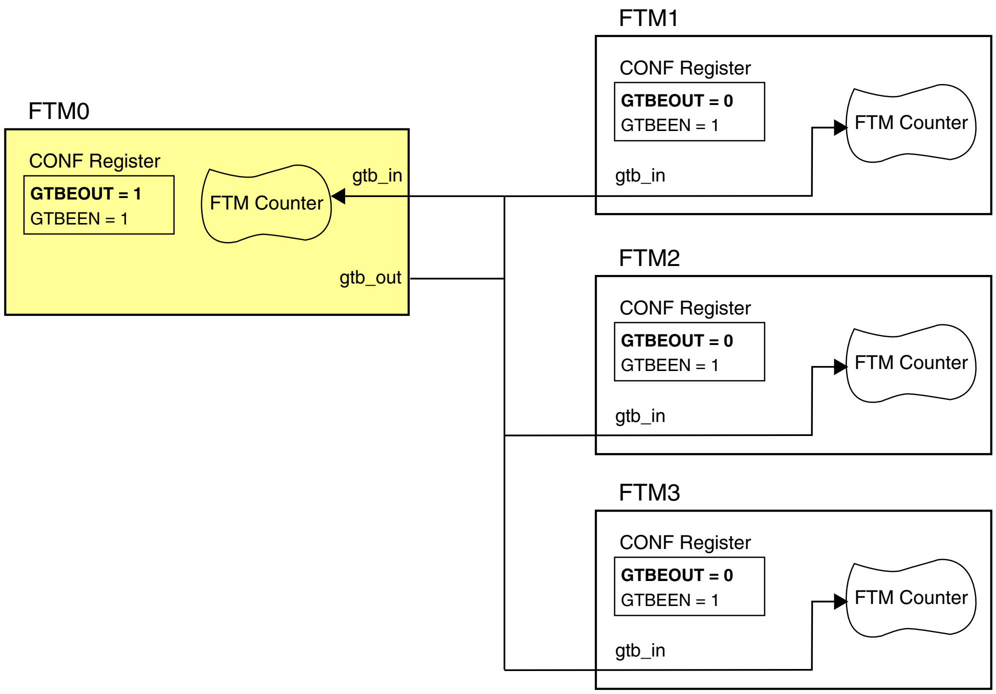

Figure 8-10. FTM Global Time Base Configuration

8.6.1.5 FTM Fault Detection Inputs

Fault inputs are useful for motor control. For motor control applications, the inputs come from a comparator. This device doesn't have an on-chip comparator; however, this device can still be used for Motor control. External interrupts (or GPIOs) from a comparator on the board can be used to indicate Fault inputs from the Motor.

In this case, the SRC would include the four Fault Inputs bits. Whenever a fault is asserted, software can write the appropriate register in SRC and this value will be driven internally to FTM.

8.6.2 Programmable Interrupt Timer(PIT)

8.6.2.1 PIT Instantiations

This device contains one PIT module with eight channels.

8.6.2.2 PIT/DMA Periodic Trigger Assignments

The PIT generates periodic trigger events to the DMA Mux as shown in the table below.

Table 8-8. PIT channel assignments for periodic DMA triggering

DMA Channel Number	PIT Channel
DMA Channel 0	PIT Channel 0
DMA Channel 1	PIT Channel 1
DMA Channel 2	PIT Channel 2
DMA Channel 3	PIT Channel 3

NOTE

When DMA channel is enabled with periodic triggering capability, and using "always enabled" DMA sources, PIT trigger is ignored.

NOTE

To implement gating the request from "always enabled" source, follow the steps below to re-assert the request:

1. Set DREQ bit in DMA_TCDn_CSR register and DMAMUX_CHCFGn[ENBL] = 0
2. Set DMAMUX_CHCFGn[ENBL] = 1, DMASREQ = channel in your DMA DONE interrupt service routine so that "always enabled" source could negate its request. Then, DMA request could be negated.

8.6.3 Programmable Delay Block (PDB)

8.6.3.1 PDB Instantiation

This device has one instance of PDB.

8.6.3.1.1 PDB Output Triggers

Table 8-9. PDB Output Triggers

PDB Parameter	Value
Number of ADC channels	2
Number of pre-triggers per ADC channel	2
Number of DAC interval triggers	2
PulseOut channels	None

8.6.3.1.2 PDB Input Trigger Connections

Table 8-10. PDB Input Trigger Options

PDB Trigger	PDB Input
0000	External Trigger at RGPIO[25]
0001	PIT Ch 0 Output
0010	PIT Ch 1 Output
0011	PIT Ch 2 Output
0100	PIT Ch 3 Output
0101	PIT Ch 4 Output
0110	PIT Ch 5 Output
0111	PIT Ch 6 Output
1000	Init and Ext Triggers from FTM0
1001	Init and Ext Triggers from FTM1
1010	Init and Ext Triggers from FTM2
1011	Init and Ext Triggers from FTM3
1101	RTC Alarm
1110	LPT Output
1111	Software Trigger

8.6.3.2 PDB Module Interconnections

PDB trigger outputs	Connection
Channel 0 triggers	ADC0 trigger
Channel 1 triggers	ADC1 trigger

8.6.3.3 DMA support on PDB

The PDB supports the DMA request functionality. One DMA request is supported.

8.6.3.4 PDB in Low-Power modes

PDB is available in the WAIT, LPRUN, UPLRUN, and STOP modes. However, the PDB is in power-gated domain and is not available in the LPSTOP1, LPSTOP2, and LPSTOP3 Low-Power Stop modes. In Low-Power Stop modes, the ADC is triggered using the Low-Power Timer (LPTMR).

8.6.3.5 PDB implementation with ADC

The following figure illustrates the implementation of the PDB interface with ADC. There is one back-to-back acknowledgement from the ADC0 to channel 0 of the PDB. In this MCU, PDB back-to-back acknowledgment connection is implemented as follows:

- PDB channel 1 pre-trigger 0 acknowledgement input: ADC0SC1B_COCO

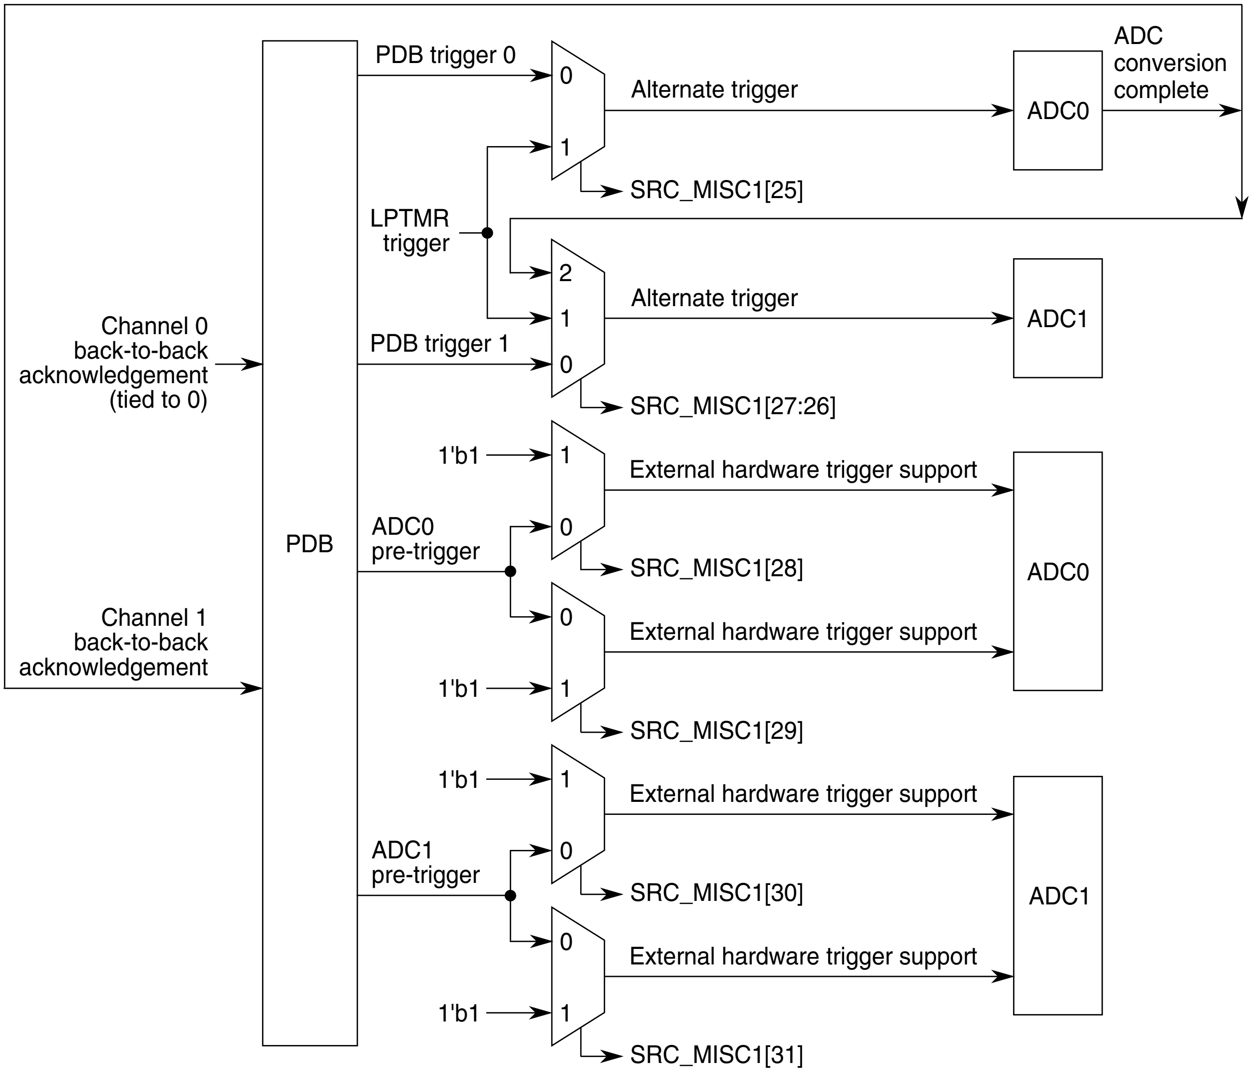

Figure 8-11. PDB implementation with ADC

8.6.4 Low-Power Timer (LPTMR)

8.6.4.1 LPTMR prescaler/glitch filter clocking options

The prescaler and glitch filter of the LPTMR module can be clocked from one of four sources determined by the LPTMR0_PSR[PCS] bitfield. The following table shows the chip-specific clock assignments for this bitfield.

NOTE

The chosen clock must remain enabled if the LPTMR is to continue operating in all required low-power modes.

LPTMR0_PSR[PCS]	Prescaler/glitch filter clock number	Chip clock
00	0	24MHz FIRC
01	1	1KHz Derived from SIRC
10	2	32KHz SXOSC
11	3	128KHz SIRC

To read about clocking on this device, refer to Clocking Overview.

8.6.5 External memory interfaces

8.6.5.1 Quad SPI

8.6.5.1.1 QuadSPI Instances

There are two instances of the QuadSPI module on this device. QuadSPI 0 supports two serial flash ports, while QuadSPI 1 supports a single serial flash port. Each QuadSPI port implements two chip-selects (CS) enabling two separate serial flashes to be attached to each individual port. The dual CS arrangement also allows dual-die packaged serial flash to be connected to a single port of a QuadSPI. The 2-port configuration of QuadSPI 0 allows two external flash devices to operate in a parallel read mode with read data from the flashes being recombined automatically in the QuadSPI module. This effectively enables an 8-bit flash interface, doubling the read bandwidth and is particularly useful for

XiP operation of fast fetch of graphics data from the external flash. Each QuadSPI4 implements a flexible 1 KB AHB buffer which can be configured in accordance with application needs.

Table 8-11. Module Instances

QuadSPI	Serial Flash Ports	# CS per Port	Parallel Mode	AHB Buffer Size	Peak DDR Read Bandwidth
QuadSPI 0	2	2	Yes	1 KB	132 MB
QuadSPI 1	1	1	No	1 KB	66 MB

QuadSPI 0 and QuadSPI 1 are available as multiplexing options on all package variants.

NOTE

Quadspi DQS Loopback mode is not supported on this device. Any reference to it in this document should be ignored.

8.6.5.1.2 QuadSPI Memory Interface

Each port of QuadSPI supports the following signals:

- SCK: Serial Clock
- IO[0:3] : Serial I/O for command, address and data
- /CS: Chip Select
- /CS2: Chip Select 2; used to select second instance of QuadSPI or select a second flash device sharing SCK and IO[0:3]
- DQS: Data strobe signal for some manufacturers for DDR read timing at 50 MHz and above

8.6.5.1.3 QuadSPI Buffer

Each QuadSPI 4 implements a flexible AHB buffer scheme to support multiple data streams the. The buffer can be partitioned into four separate buffers of different size, each associated to specific bus masters. In addition, the buffers can be associated with one or other of the connected serial flashes or both simultaneously. For details on configuration of the AHB buffers, refer to the QuadSPI chapter in this reference manual.

8.6.5.1.4 Booting from QuadSPI

Available frequency in System Boot for booting through QuadsSPI0 with multiple configuration (SDR, DDR modes):

Table 8-12. Booting from QuadSPI

	QuadSPI 0 in DDR Mode	QuadSPI 0 in SDR Mode
SCK frequency options in MHz	18	18, 60, 74

8.6.6 DRAM Controller

8.6.6.1 DDR maximum address space

The maximum address space available for the DDR controller is calculated using the following formula:

$$\text{Maximum Memory Size} = \text{Chip\_Selects} \times \text{Banks} \times 2^{\text{Address\_bits}} \times \text{Data\_Path\_Width}$$

The maximum values available for this device are:

- Chip selects = 1
- Device address = 16 rows + 10 columns = 26
- Number of banks = 8
- Memory data path width = 2 bytes

As a result, the maximum accessible memory area is 1 GB.

The address map for this configuration is shown below. Address bits 30–31 are not used. These bits are ignored when generating the address to the DRAM devices.

Bits	31 30	29	28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13	12 11 10	9 8 7 6 5 4 3 2 1	0
Field	Don't care	Chip select	Row	Bank	Column	Data path

Figure 8-12. Alternate memory map

8.6.7 Nand Flash Controller

8.6.7.1 Instantiation

The NAND Flash Controller(NFC) interfaces standard NAND Flash devices to the IC and hides the complexities of accessing the NAND Flash. It provides a glueless interface to both 8-bit and 16-bit NAND Flash parts with page sizes of 512 bytes, 2 kilobytes, 4 kilobytes and 8 kilobytes.

8.6.8 FlexBus Controller

8.6.8.1 FlexBus signal multiplexing

The multiplexing of the FlexBus address and data signals is controlled by the port control module. However, the multiplexing of some of the FlexBus control signals is controlled by the port control and FlexBus modules. The port control module registers control whether the FlexBus or another module signals are available on the external pin, while the FlexBus's CSPMCR register configures which FlexBus signals are available from the module. The control signals are grouped as illustrated:

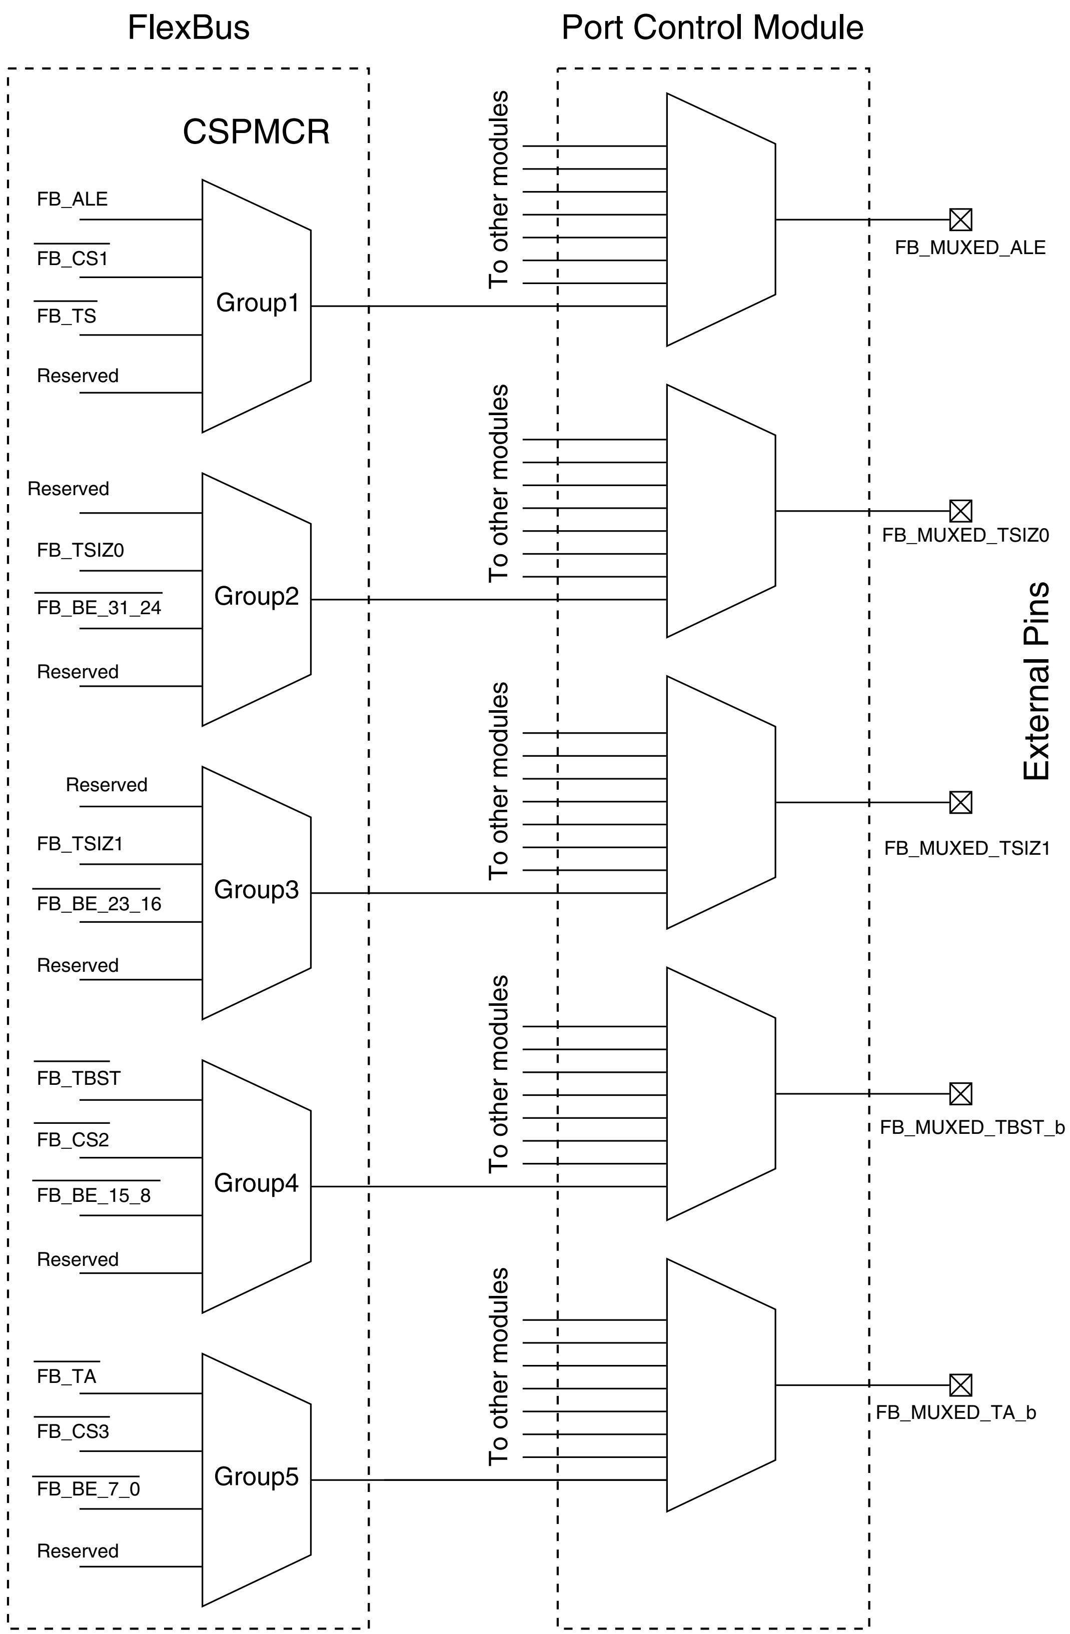

Figure 8-13. FlexBus control signal multiplexing

Therefore, use the CSPMCR and port control registers to configure which control signal is available on the external pin.

8.6.8.2 FlexBus Signal Multiplexing

The table below shows the FlexBus signal multiplexing on this device.

Table 8-13. FlexBus Multiplexing

Flexbus Signal	CSPMCR bits	Value of CSPMCR bits	Pad Connected to	Pin Connected to	ALT Mode	Signal Name
FB_ALE	[31:28]	0	PAD[93]	PTB23	ALT4	FB_MUXED_ALE
FB_CS1_b		1				
FB_TS_b		2				
Reserved		Rest				
Reserved	[27:24]	0	PAD[94]	PTB24	ALT4	FB_MUXED_TSIZ0
FB_SIZE[0]		1				
FE_BE_31_24_b		2				
Reserved		Rest				
Reserved	[23:20]	0	PAD[102]	PTC29	ALT5	FB_MUXED_TSIZ1
FB_SIZE[1]		1				
FB_BE_23_16_b		2				
Reserved		Rest				
FB_TBST_b	[19:16]	0	PAD[97]	PTB27	ALT5	FB_MUXED_TBST_b
FB_CS2_b		1				
FB_BE_15_8_b		2				
Reserved		Rest				
FB_TA_b	[15:12]	0	PAD[103]	PTC30	ALT4	FB_MUXED_BE0_b
FB_CS3_b		1				
FB_BE_7_0_b		2				
Reserved		Rest				

8.6.8.3 FlexBus External Signal

The following sections correlate the chip-level signal with the signal name used in the module's chapter.

Table 8-14. External Signals

Chip signal name	Module Signal name
FB_BE3_B	FB_BE31_24_B
FB_BE2_B	FB_BE23_16_B
FB_BE1_B	FB_BE15_8_B
FB_BE0_B	FB_BE7_0_B

8.6.8.4 FlexBus Security

FlexBus accesses are moderated by AHB TrustZone that is part of platform.

8.6.8.5 Instantiation Information

The FlexBus module is pinned out with a 32-bit multiplexed address and data bus with four chip selects. The bus allows for the configurations listed in the table below. In configurations where the full 32-bit bus is not needed those signals can be used as GPIO or other multiplexed functions.

NOTE

By default, FlexBus clocks are disabled and have to be explicitly enabled by software.

NOTE

Any access to the FlexBus device without clocks initialized may hang the bus.

Table 8-15. FlexBus Configurations

Number of Address Lines	Number of Data Lines	Number of External Signals	CSCR[bit 9] setting	Mode
32	32/16/8	32 (FB_AD[31:0])	1	Multiplexed FB_AD[31:0] allows for full 32-bit address with multiplexed 32-bit, 16-bit, or 8-bit data. 8-bit data comes out on FB_AD[7:0].

Table continues on the next page...

Table 8-15. FlexBus Configurations (continued)

Number of Address Lines	Number of Data Lines	Number of External Signals	CSCR[bit 9] setting	Mode
24 or less	16/8	24 or less (FB_AD[23:0])	1	Multiplexed FB_AD[23:0] allows for up to 24 address lines with multiplexed 16-bit or 8-bit data. 8-bit data comes out on FB_AD[7:0]
24 or less	8	32 or less (FB_AD[23:0] + FB_AD[31:24])	0	Non-multiplexed mode. FB_A[24:0] are dedicated address lines. FB_D[7:0] (FB_AD[31:24] internally) are used as dedicated data lines.
16 or less	16	32 or less (FB_AD[15:0] + FB_AD[31:16])	0	Non-multiplexed mode. FB_A[15:0] are dedicated address lines. FB_D[15:0] (FB_AD[31:16] internally) are used as dedicated data lines.
0	32/16/8	32, 16, or 8 (FB_AD[31:0], FB_AD[31:16]/ FB_AD[15:0], or FB_AD[31:24/ FB_AD[7:0])	0 or 1	Data only mode. Commonly used for interfacing to smart LCD devices. Support 32-bit, 16-bit, or 8-bt data. Either the upper or lower half of the data bus can be used as selected by CSCR[bit 9].

8.6.8.6 FlexBus Chip Select Control Register (CSCR0) Reset Value

On this device the Chip Select Control Register (CSCR0) resets to 0x003F_FC00. Configure this register as needed before performing any FlexBus acccess.

For more information about CSCR0 control bits, see Chip Select Control Register (FB_CSCR*n*).

8.6.8.7 Bus Timeout

For scenarios where auto-acknowledge feature is disabled, device can hang if there is no external FB_TA_b received. To avoid this scenario, a monitor is provided that terminates a FlexBus transaction as bus error if it does not complete within the specified time. Refer to SRC_MISC3 register description in System Reset Controller to get details about the configuration of this counter.

8.7 Communication interfaces

8.7.1 10/100 Ethernet Subsystem

8.7.1.1 Instantiation Information

Vybrid family devices will instantiate Ethernet modules as shown below.

Table 8-16. Ethernet Instantiations

	176 LQFP	364 BGA
10/100 Ethernet (MAC-NET	2	2
L2 Ethernet Switch	None	1

NOTE

1. No true AVB supported. This would be done by restricting the ethernet traffic for only Audio and Video data and managing the priority in firmware.
2. MII mode is supported for MAC0 only and when MII mode for MAC0 is enabled, RMII of MAC1 cannot be used.

8.7.1.2 MII and RMII configuration

MII is a 4-bit interface, which is clocked at 25 MHz to support 100 Mbits/sec and RMII is a 2-bit interface clock at 50 MHz to support same data rate. This device has two Ethernet MACs. MAC0 has been configured to support both RMII and MII, while MAC1 has been configured to support only RMII. Further, if MII interface on MAC0 is enabled, MAC1 cannot be used for RMII interface. Various Pins used in RMII and MII for MAC0 and the pins that can be used are described below.

Table 8-17. MII and RMII configuration for MAC0

Ethernet Signal Name	Description	Pin Configuration in MII mode	Pin Configuration in RMII mode
Transmitter Signals			
TXD0	Transmit data bit 0 (MAC to PHY)	PAD_51-ALT1	PAD_51-ALT1
TXD1	Transmit data bit 1 (MAC to PHY)	PAD_52-ALT1	PAD_52-ALT1
TXD2	Transmit data bit 2 (MAC to PHY)	PAD_76-ALT6	Not used in RMII mode
TXD3	Transmit data bit 3 (MAC to PHY)	PAD_75-ALT6	Not used in RMII mode
TXEN	Transmit data valid(MAC to PHY)	PAD_53-ALT1	PAD_53-ALT1
TXER TXCLK	Transmit data error(MAC to PHY)	PAD_77-ALT6	Not used in RMII mode
TXCLK	Transmit Clock (PHY to MAC. Can be internal for RMII as well.)	PAD_0-ALT2/ PAD2-ALT3	Both TX and RX clock in RMII mode are muxed into one signal. The source can be either: PAD_0-ALT2/ PAD2-ALT3/PLL5 main clock/Audio Ext clock as explained in Section 9.11.6 Ethernet RMII Clocking.
Receiver Signals			
RXD0	Receive bit 0 (PHY to MAC)	PAD_49-ALT1	PAD_49-ALT1
RXD1	Receive bit 1 (PHY to MAC)	PAD_48-ALT1	PAD_48-ALT1
RXD2	Receive bit 2 (PHY to MAC)	PAD_72-ALT0 (It is shared with RGPIO, so ensure IOMUX register has obe=0 for this pin when used for MII.)	Not used in RMII mode
RXD3	Receive bit 3 (PHY to MAC)	PAD_71-ALT0 (It is shared with RGPIO, so ensure IOMUX register has obe=0 for this pin when used for MII.)	Not used in RMII mode
RXEN	Receive data valid (PHY to MAC)	PAD_47-ALT1	PAD_47-ALT1
RXER	Receive data error (PHY to MAC)	PAD_50-ALT1	PAD_50-ALT1
COL	Collision (PHY to MAC)	PAD_74-ALT0 (It is shared with RGPIO, so ensure IOMUX register has obe=0 for this pin when used for MII.)	Not used in RMII mode
CRS	Carrier Sense (PHY to MAC)	PAD_73-ALT0 (It is shared with RGPIO, so ensure IOMUX register has obe=0 for this pin when used for MII.)	Not used in RMII mode.

Table continues on the next page...

Table 8-17. MII and RMII configuration for MAC0 (continued)

Ethernet Signal Name	Description	Pin Configuration in MII mode	Pin Configuration in RMII mode
RXCLK	Receive Clock (PHY to MAC. Can be internal for RMII as well.)	PAD_11-ALT0 (It is shared with RGPIO, so ensure IOMUX register has obe=0 for this pin when used for MII.)	It is muxed with TXCLK. See above for details.
MDIO	Management I/O data (Bidirectional)	PAD_46-ALT1	PAD_46-ALT1
MDC	Management Clock (PHY to MAX. Can be internal as well.)	PAD_45-ALT1	PAD_45-ALT1

8.7.1.3 IEEE 1588 Timers

The ethernet module includes a four channel timer module for IEEE 1588 timestamping. The timer supports input capture (rising, falling, or both edges), output compare (toggle or pulse with programmable polarity). The timer matches on greater than or equal (the 1588 can skip numbers, so the counter might not ever exactly match the compare value).

The counter is able to operate asynchronously to the ethernet bus by using one of four clock sources. See Clocking Chapter for more details.

8.7.1.4 Ethernet Operation in Low Power Modes

Low Power modes with Ethernet only Operation

The Ethernet module is not fully operational in any low power modes. However, the module does support magic packet detection that can generate a wakeup in low power mode if enabled.

During low power operation:

- The MAC transmit logic is disabled
- The core FIFO receive/transmit functions are disabled
- The MAC receive logic is kept in normal mode, but it ignores all traffic from the line except magic packets.

The recieve logic needed for magic packet detection is clocked using the externally-supplied RMII clock. This allows for the wakeup functionality in low power modes.

NOTE

Wakeup from Magic Packet is supported on Vybrid STOP mode but not supported on LPSTOP1/2/3 mode.

Low Power modes with Dual Ethernet and L2 Switch operation

In low power mode(STOP mode) , the ENET stops immediately and freezes operation, register values, state machines, and external pins. During this mode, the ENET clocks are shut down. Coming out of stop mode returns the ENET to operation from the state prior to stop mode entry.

NOTE

Practically this would not occur as system would not go in Stop Mode during this mode. CPU enters or executes a stop instruction for the system to go in Stop mode (low power mode) when it sees inactivity or when the system is in idle state for a long period of time. Incase there is no activity on the Ethernet Bus or no packets to forward to the other port, CPU may enter this mode. In that case, ENET should have the capability to wake up from stop mode incase of activity on Ethernet bus for the system to exit this mode (RMII clock would still be ONN to interrupt the processor on looking at any activity on the RMII bus).

Low Power modes with Dual Ethernet and L2 Switch Bypassed

In this mode, the ENET stops immediately and freezes operation, register values, state machines, and external pins. During this mode, the ENET clocks are shut down. Coming out of low power mode returns the ENET to operation from the state prior to low power mode entry.

NOTE

Any activity on the Ethernet Bus (RMII/MII interface) would wake up the system and would exist from the low power mode. Similar to the previous case, system would not enter into this mode practically incase of an ongoing activity on packet transmission via RMII interface.

Battery mode of operation

The ENET does not support any Standby Mode of operation or a capability to operate on battery incase the main supply fails. The ENET would be disabled during this Mode.

8.7.1.5 Ethernet Subsystem Interrupts

The Ethernet has multiple sources of interrupt requests. However, some of these sources are OR'd together to generate an interrupt request. See below for a summary:

Interrupt request	Interrupt source
ENET interrupt	• Transmit frame interrupt • Transmit buffer interrupt • Receive frame interrupt • Receive buffer interrupt • Wake-up • Payload receive error • Babbling receive error • Babbling transmit error • Graceful stop complete • MII interrupt – Data transfer done • Ethernet bus error • Late collision • Collision retry limit
IEEE 1588 timer interrupt	• Time stamp available • 1588 timer interrupt
Ethernet Switch interrupt	• Learning Interrupt • Output Discard for port 0 (OD0) • Output Discard for port 1 (OD1) • Output Discard for port 2 (OD2) • Receive Buffer Interrupt • Receive Frame Interrupt • Transmit Buffer Interrupt • Transmit Frame Interrupt

8.7.1.6 Ethernet switch register reset values

Some of the Ethernet Switch registers have reset values that are specific to this device. These registers and reset values are listed below and supersede the default reset values given in the Ethernet Switch chapter.

Table 8-18. Device-specific reset values

Register	Reset value
ESW_REV	0x0001_0130

8.7.2 USB 2.0 HS/FS/LS Dual Role (Host / Device) Controller

8.7.2.1 USB Configuration and Options

USB Subsystem includes the following:-

- USB 2.0 HS/FS/LS Dual Role (Host / Device) Controller (x2)
- HS 2.0 integrated PHY (x 2)

8.7.2.2 USB Host initialization and bring up

Table 8-19. Steps to start USB in Device mode

Initialization
• Power ON Vybrid. • With all the regulators activated, they generate OK. Once, all regulators are up and OK will release functional reset. • The Core works on 24 Mhz IRC. It initializes the registers, configures generic interrupt controller, and initializes interrupt handlers. • Enable 24 MHz XTAL. • Once, XTAL OK is asserted, enables all PLL (mainly SYS PLL).   • Wait for PLL Lock. (Get status from ANADIG PLL registers.) • After PLL are Locked, disable Clock gating and disable the bypass for PLL. • Switch the Clocks to PLL Clock. • Switch to USB specific configuration for running USB and initialize USB specific features with Vybrid.
Initializaing USB specific features

Table continues on the next page...

Table 8-19. Steps to start USB in Device mode (continued)

• Disable the on-chip oscillator (XOSC 24M) powerdown in next powerdown.
  • In register CCM Low Power control register (CCM_CLPCR) dessert SBYOS bit. CCM_CLPCR[SBYOS]= 0.
• Enable the USB regulator. Set bit# 0 (ENABLE_LINREG) in register ANADIG Regulator 3P0 definition register (Anadig_REG_3P0). This regulator works on 5V supply. This needs to be driven from outside the chip.
• Enable USB PLL and enable usb clocks: In ANADIG register–(Anadig_USB1_PLL_CTRL) and (Anadig_USB2_PLL_CTRL) enable EN_USB_CLKS and disable BYPASS, that is,
  • Anadig_USB1_PLL_CTRL[POWER]=1
  • Anadig_USB1_PLL_CTRL[EN_USB_CLKS]=1
  • Anadig_USB1_PLL_CTRL[BYPASS]=0
• Start the USB PHY –
  • Disable Soft reset of USB PHY – USBPHY_CTRLn[SFTRST]=0
  • Enable USB Clocks – USBPHY_CTRLn[CLKGATE]=0
  • For running the controller in LS mode, user needs to set bit#15 (ENUTMILEVEL3) and bit#14 (ENUTMILEVEL2)
  • In USB PHY Power-Down Register (USBPHY_PWD) clear all the bits and set them to zero. Anadig[USBPHY_PWD]= 0x0000_0000
• Optionally, one can enable the interrupt of USB controller going to the processor ARM Generic Interrupt Controller (GIC)-Enable Interrupt ID 107 (USB0) and Enable Interrupt ID 108 (USB1).
• The user can set the WIE bit, if the GIC bit is configured. USBC0_CTRL[WIE]=1
• Refer to “Starting USB Controller in HOST Mode”. Once, controller is set to host mode, user can start to next step.
• Setup Memory for the USB controller to start communication:
  • Configure the memory as per “Configure the USB controller to read the descriptor from the connected device and Set Address” for setting up memory for starting communication.
• User can wait for the device to detect, configure and connect for starting communication over USB. Refer to Detection for port status change, resetting the USB and speed of connected device.
• Once the setup is complete--device connected and configured. One can start communication over usb. Refer to Starting the communication over the USB from Configured Connected Device.

Starting USB Controller in Host Mode

• By default the USB on Vybrid is defaulted to device controller. For initializing them as a Host user has to do following steps:
  • In USB_OTG1_USBCMD register, set the RST bit
  • Keeping polling for de-assertion of this bit.
  • In USBMODE register configure CM bit, that is, bit 1 and bit 0
  • Keep polling and writing back 2’b11 on CM if bit are not set to 11.
  • Once these bits are set to 11, controller is configured to function like a host.
  • Refer to “Setting Up device controller” for setup device interrupt and periodic index .
  • If Port Power is required then refer to “Enable the port power in device Controller”

Enable the port power in Host controller
• In register Host Controller Structural Parameters (USBx_HCSPARAMS), read if implementation allows controlling the port power. If it reads back to ‘1’, indicates the port power can be controlled. In that case, we can configure bit number 12 of Port Status & Control (USBx_PORTSC1) register to enable port power.
Setting Up Host controller
• Setting Up interrupt threshold–In USB Command Register (USBx_USBCMD), set ITC bit to zero. Else set ITC bit as per system needs. • In USB Frame Index (USBx_FRINDEX), write 1 to the to FRINDEX. This register is used by the host controller to index the periodic frame list. The register updates every 125 microseconds (once each micro-frame). Moreover, this register cannot be written unless the Host Controller is in the 'Halted' state as indicated by the HCHalted bit inside USB Status Register (USBx_USBSTS).
Detection for port status change, resetting the USB and speed of connected device

Table continues on the next page...

Table 8-19. Steps to start USB in Device mode (continued)

- Everything is set, now user can wait for connection of any external device to the host controller. To sense the device attached, user can poll or configure an interrupt waiting for USB_OTG1_USBSTS to check the change in the port status.
  - Once bit2 of PCI bit is found asserted; dessert this bit by writing back 1 to the same location. This is W1C bit.
  - Poll for PORTSC0 register, bit #1, Current Status Change (CSC). If set to ‘1’, set port change is detected. Now clear this bit by writing back ‘1’ into the same location.
  - Check the connect status—Bit#0 of register OTG_PORTSC0. If found asserted port is connected. Else disconnect or under enumeration.
  - Check if UTMI clocks are OK in USBNC registers – USBCx_PHY – bit# 31.
  - Reset the USB port
    - IN USB Command Register (USBx_USBCMD), set RS bit#0. To start the controller.
    - Check bit#12 in USBSTS register – HCH. If set to 1, controller is in halted state.
  - Set bit#8 of PORTSC0 register for starting the reset sequence. Once this bit is written with 1, controller will start reset sequence (CHRIP) for that port.
    - Wait for USB_PORTSC[PR] bit to clear.
    - Now check for bit#2 of PORTSC register to check if the device is not disconnected due to reset sequence. If not, move to next step, else restart from “Detection for port change”.
    - Now check bit#27:26 of PORTSC register to check the port speed. If PSPD is found to be:
      - 00 – Full speed
      - 01 – Low speed
      - 10 – High speed

      If found not connected, restart from “Detection for port change”.

- Configure the host controller to create channel between software running at processor and the device connected.
  - The populated data structure for communication between the software and the device is kept in the memory. This structure needs to be kept at 64 byte aligned boundary address. The base address of this data structure needs to be loaded inside the controller to operate.
  - This address needs to be loaded at USB_OTG1_ASYNCLISTADDR.

Configure the USB controller to read the descriptor from the connected device and Set Address

- Refer the EHCI Documentation for detailed configuration and running the USB. The method shown here is one of the method for Writing Software for running the USB on Vybrid.
- USB memory need to be initialized to get configured, check features and set address for starting communication over USB.
  - Populate the Asynchronous Queue in Memory.
    - Get device feature: Reading control descriptor \ Communicate to EP0, ADD0, read Descriptor.
    - Assign Address: If readback features are supported, and need not to suspend the USB port then assign Address.
    - Once address assignment is done, populate to new QTHead where further communication to happen with new address.
    - Read feature descriptor allocated to other endpoint of the connected device.
    - Once, all the device feature are read, firmware can communicate with device accordingly to access and control different feature by populating qTD for the feature.
- The user needs to populate “Periodic framelist ” for isochronous and interrupt transfers and “asynchronous list” for control and bulk transfers.
  - For running the controller in FS mode, user needs to set endpoint speed to FS in endpoint control populated in the memory. For LS mode, user need to set the endpoint to LS in endpoint control populated in the memory.
  - User has to dump the periodic framelist baseaddress into Frame List Base Address (USBx_PERIODICLISTBASE) register .
  - For Async transfer, user has to dump async framelist base address into Asynch. Address (USBx_ASYNCLISTADDR)
  - Please refer section " Host Data Structures” for more information on Periodic and Asynchronous Framelist.

- Now, controller waits for any device to connect. Once there is any port status change, controller will generate interrupt to the processor.
- In register USBSTS, poll for USB Status, bit#0 for completion of command list given through Asynchronous queue.

Table continues on the next page...

Table 8-19. Steps to start USB in Device mode (continued)

Starting the communication over the USB from Configured Connected Device

• Refer the EHCI documentation for detailed configuration and running the USB. The method shown here is one of the method for Writing Software for running the USB on Vybrid.
• Read the “Host Data Structures” Vybrid RM.
• User needs to set following:
    • Programming the endpoint capabilities/characteristics in the queue head with the capabilities of the endpoint and device to communicate. User can program following things in the register: Endpoint number, Endpoint speed, Endpoint max packet length, and device address .
    • Program the page offset in the queue head. Each page carries a packet to be transmitted. User can actually check the status of the transmission by looking into “Current qTD pointer”, “Next qTD pointer”, and “Alternate qTD pointer”
    • In register USBSTS, poll for USB Status, bit#0 for completion of command list given through Asynchronous queue.
• After populating the entire structure into the memory, user has to set bit#7 in qTD token status. This bit is set by the software to enable the execution of transaction by the Host controller. Keep polling the remaining bits [6:0] for different communication issues.

8.7.2.3 SOF for USB Audio

This is mainly applicable when Dual Role (Host / Device) Controller is working in Device Mode. For some of the USB Audio use-cases, require some sort of audio clock recovery capability. One way to do it is to use the Start of Frame (SOF) signal which is generated at the start of a microframe in the USB 2.0 HS. This is a signal with a rate of 125 microseconds. When operating in Full Speed mode, the SOF signal has a rate of 1 ms.

Pulse that asserts for 64 system clock cycles when the SOF token is detected on the USB bus when the USB controller is in device mode.

In order to properly support USB Audio Isochronous Asynchronous mode of operation, it is necessary to measure how many audio sample clock ticks occur between two consecutive occurrences of the SOF signal. This measurement is used to provide feedback to the USB audio source in order to speed up or slow down the audio sample delivery over the USB bus.

This is the method of estimating the ratio between the USB Host clock (SOF occurrences) and the local audio clock.

Figure below shows the USB SOF connectivity with FlexTimer to enable this scheme.

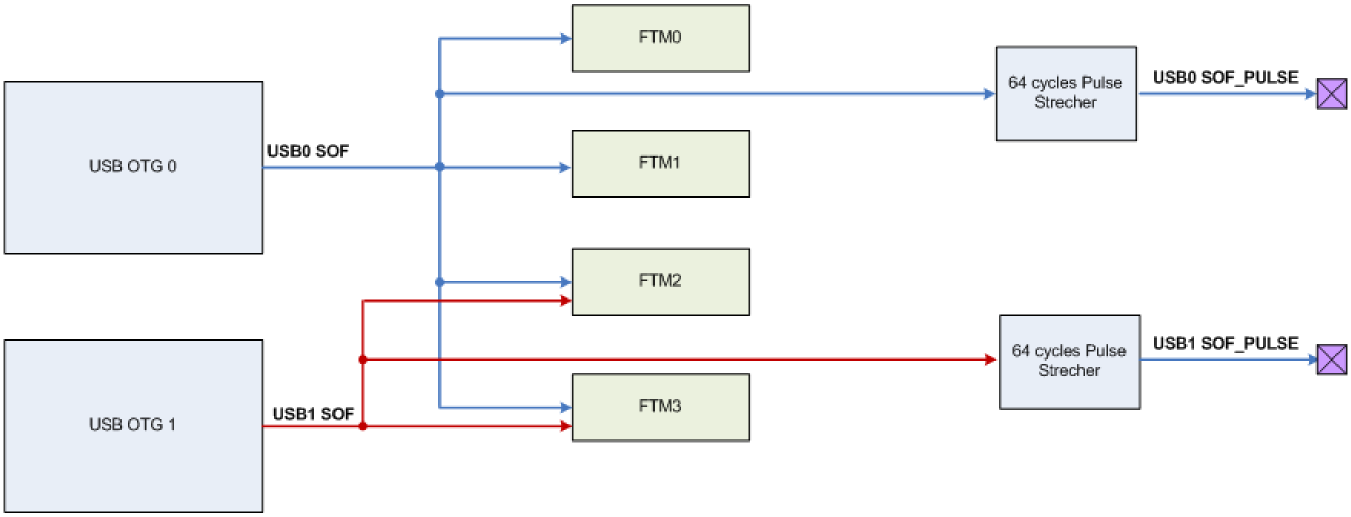

Figure 8-14. USB SOF connectivity with Flextimer

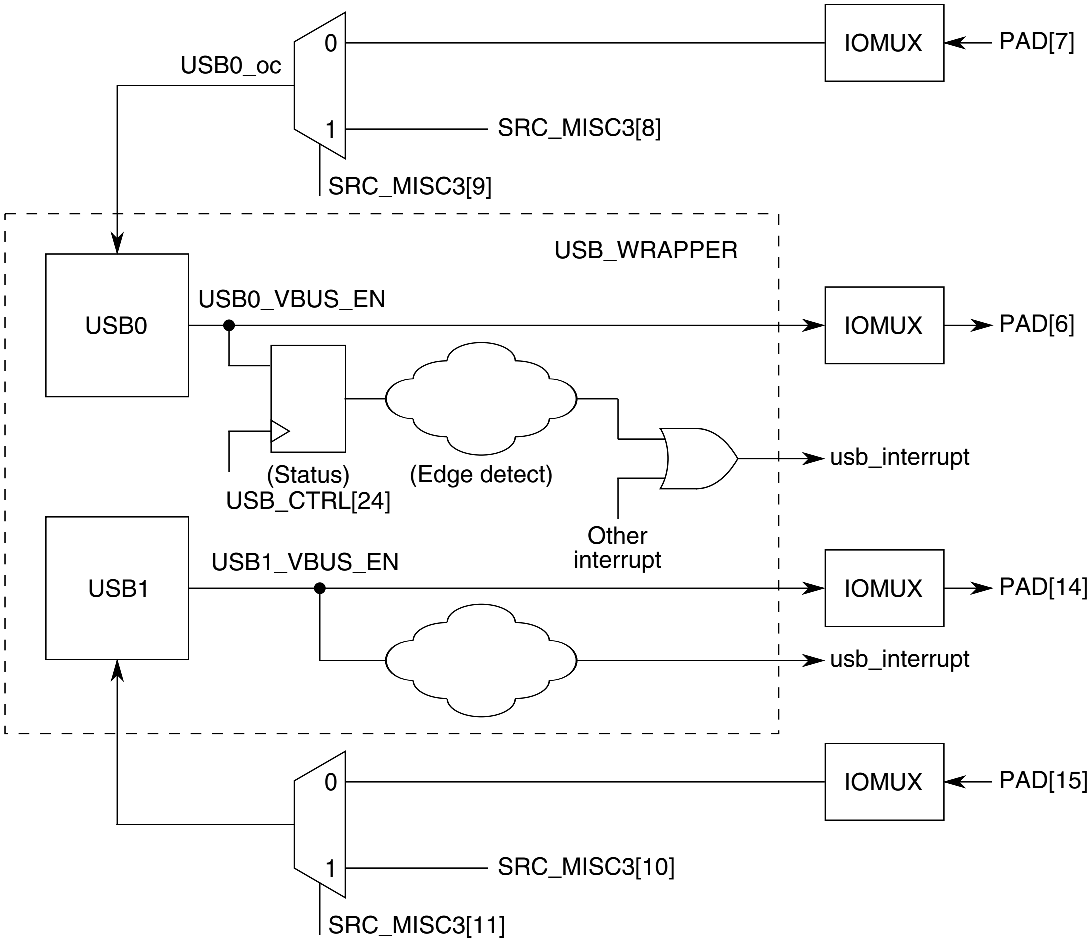
1. The two SOF signals (one from each USB port) must be brought to two timers channels of one FlexTimer. This flexibility is provided in FTM2 and FTM3 as shown in figure.
2. At least one of the SOF signals should be connected to one channel of a second FlexTimer. This will allow measuring of two sets of audio clock/SOF signals. To accomodate this USB0 SOF is connected to all Flextimers.

The audio master clock should also be provided as one of the clock options to FlexTimer.

8.7.2.4 OverCurrent and VBUS Connection

The figure below provides OverCurrent and VBUS Connection.



VBUS_EN is routed to PAD as well as an interrupt from USB. Its status is in USB_CTRL[24] and can be masked using USB_CTRL[25].

Figure 8-15. OverCurrent and VBUS Connection

8.7.3 Secure Digital Host Controller (SDHC)

8.7.3.1 SD bus pullup/pulldown constraints

The SD standard requires the SD bus signals (except the SD clock) to be pulled up during data transfers. The SDHC also provides a feature of detecting card insertion/removal, by detecting voltage level changes on DAT[3] of the SD bus. To support this DAT[3] must be pulled down. To avoid a situation where the SDHC detects voltage changes due to normal data transfers on the SD bus as card insertion/removal, the interrupt relating to this event must be disabled after the card has been inserted and detected. It can be re-enabled after the card is removed.

8.7.3.2 SDHC Wakeup

The SDHC controller is taken out of low power mode by some of its interrupts, known as wakeup interrupts. The SDHC can generate these interrupts even when clocks are not enabled. The three interrupts which can be used as wakeup events are:

1. Card Removal Interrupt
2. Card Insertion Interrupt
3. Interrupt from SDIO card

To make the interrupt a wakeup event, when all the clocks to the SDHC are disabled or when the whole system is in low power mode, the corresponding wakeup enabled bit needs to be set.

8.7.3.2.1 Setting Wake Up Events

For the SDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters sleep mode. Before the software disables the host clock, it should ensure that all of the following conditions have been met:

- No Read or Write Transfer is active
- Data and Command lines are not active
- No interrupts are pending
- Internal data buffer is empty

8.7.3.3 SDHC Software Guidelines

SDHC interrupt does not set under the following circumstances:

1. SDHC configured to generate wakeup on card interrupt. PLL3 is selected as SDHC's baud rate clock.
2. ESDHC clocks are disabled by SDHC_SYSCTL register. For details about the register, refer to the respective chapter in this document.
3. PLLs are powered down by software before entering into STOP mode.
4. ESDHC wakeup occurs because of card interrupt.
5. Bus clock restarts but PLL does not start as software directly jumps to SDHC ISR instead of PLL enabling routine.
6. CPU reads SDHC_IRQSTAT register, but finds no bit set. The bit requires baud rate clock to get set, which needs PLL3 to get powered up.

8.7.4 UART

8.7.4.1 UART configuration information

This device contains up to six UART modules. This section describes how each module is configured on this device.

1. Standard features of all UARTs:
    - RS-485 support
    - Hardware flow control (RTS/CTS)
    - 9-bit UART to support address mark with parity
    - MSB/LSB configuration on data
2. All UARTs are clocked on the IPS bus clock. The maximum baud rate is 1/16 of related source clock frequency.
3. IrDA is available on all UARTs
4. UART0 and UART1 contains the standard features plus ISO7816
5. UART0 and UART1 contains 16-entry transmit and 16-entry receive FIFOs
6. All other UARTs contain a 8-entry transmit and 8-entry receive FIFOs
7. LON is available in UART0 and UART1
8. LIN 2.0 supported on all UARTs.

8.7.4.2 UART wakeup

The UART can be configured to generate an interrupt/wakeup on the first active edge that it receives.

8.7.4.3 UART interrupts

The UART has multiple sources of interrupt requests. However, some of these sources are OR'd together to generate a single interrupt request. See below for the mapping of the individual interrupt sources to the interrupt request:

The status interrupt combines the following interrupt sources:

Source	UART 0	UART 1	UART 2	UART 3	UART 4	UART 5
Transmit data empty	x	x	x	x	x	x

Table continues on the next page...

Source	UART 0	UART 1	UART 2	UART 3	UART 4	UART 5
Transmit complete	x	x	x	x	x	x
Idle line	x	x	x	x	x	x
Receive data full	x	x	x	x	x	x
LIN break detect	x	x	x	x	x	x
RxD pin active edge	x	x	x	x	x	x
Initial character detect	x	x	—	—	—	—

The error interrupt combines the following interrupt sources:

Source	UART 0	UART 1	UART 2	UART 3	UART 4	UART 5
Receiver overrun	x	x	x	x	x	x
Noise flag	x	x	x	x	x	x
Framing error	x	x	x	x	x	x
Parity error	x	x	x	x	x	x
Transmitter buffer overflow	x	x	x	x	x	x
Receiver buffer underflow	x	x	x	x	x	x
Transmit threshold	x	x	—	—	—	—
Receiver threshold	x	x	—	—	—	—
Wait timer	x	x	—	—	—	—
Character wait timer	x	x	—	—	—	—
Block wait timer	x	x	—	—	—	—
Guard time violation	x	x	—	—	—	—

8.7.4.4 UART Instances Register Difference

In this device, UART2, UART3, UART4, and UART5 do not support 7816 and Lon (CEA709) features. Therefore, these UART instances do not contain the respective registers. The following registers are not supported by UART2, UART3, UART4, UART5 instances in this devices.

Table 8-20. UART Instances Register Difference

Registers	UART0	UART1	UART2	UART3	UART4	UART5
UART 7816 Control Register	X	X	–	–	–	–
UART 7816 Interrupt Enable Register	X	X	–	–	–	–
UART 7816 Interrupt Status Register	X	X	–	–	–	–
UART 7816 Wait Parameter Register	X	X	–	–	–	–
UART 7816 Wait Parameter Register	X	X	–	–	–	–
UART 7816 Wait N Register	X	X	–	–	–	–
UART 7816 Wait FD Register	X	X	–	–	–	–
UART 7816 Error Threshold Register	X	X	–	–	–	–
UART 7816 Transmit Length Register	X	X	–	–	–	–
UART CEA709.1-B Packet Cycle Time Counter High	X	X	–	–	–	–
UART CEA709.1-B Packet Cycle Time Counter Low	X	X	–	–	–	–
UART CEA709.1-B Beta1 Timer (UART3_B1T)	X	X	–	–	–	–

Table continues on the next page...

Table 8-20. UART Instances Register Difference (continued)

Registers	UART0	UART1	UART2	UART3	UART4	UART5
UART CEA709.1-B Secondary Delay Timer High	X	X	–	–	–	–
UART CEA709.1-B Secondary Delay Timer Low	X	X	–	–	–	–

UART CEA709.1-B Collision Pulse Width	X	X	–	–	–	–

8.7.5 FlexCAN

8.7.5.1 Instantiation

There are two instances of the FlexCAN module on this device: FlexCAN0 and FlexCAN1.

Each FlexCAN is implemented with 64 message buffers each.

8.7.6 SPI

8.7.6.1 SPI Instantiation

This device contains up to 4 SPI modules.

Table 8-21. SPI Instances

SPI	176 LQFP	364 BGA
No. of SPI	3	4
SPI0 CTAR	4	4
SPI1 CTAR	2	2
SPI2 CTAR	2	2
SPI3 CTAR	N/A	2
SPI0 Chip Selects	6	6
SPI1 Chip Selects	4	4
SPI2 Chip Selects	2	2
SPI3 Chip Selects	N/A	2
TX FIFO SPI0	4	4
RX FIFO SPI0	4	4
TX FIFO SPI1	4	4
RX FIFO SPI1	4	4
TX FIFO SPI2	4	4
RX FIFO SPI2	4	4
TX FIFO SPI3	N/A	4
RX FIFO SPI3	N/A	4

NOTE

The SPI's de-serial interface (DSI) and timed serial bus (TSB) features are not supported on any SPI instance

The SPI module is clocked by the internal bus clock. The module has an internal divider, with a minimum divide of two. Thus, the SPI can run at a maximum frequency of bus clock/2.

8.7.6.2 Number of PCS

Depending on the number of DSPI instances, the number of PCS varies from 2 to 6.

For :
- DSPI0 - 6
- DSPI1 - 4
- DSPI2 - 2
- DSPI3 - 2

8.7.7 Inter-Integrated Circuit (I2C)

8.7.7.1 Instantiation Information

This device contains up to four I2C modules, I2C0, I2C1, I2C2, and I2C3.

8.8 Analog

8.8.1 12-bit Analog to Digital Converter (ADC)

8.8.1.1 ADC Instantiation

This device contains a total of 16 ADC pin inputs. The ADC signals are distributed around the chip in order to optimize the flexibility in layout and feature trade off for the user.

The ADC conversion channel is selected by setting the Pin Mux control bit.

The 176 LQFP packages do not bond out the VREFL and VREFH pins. 364 BGA offers dedicated ADC channels on pads apart from ADC channels muxed with GPIO.

Features	176 LQFP	364 BGA
No of ADC	2	2
No of Differential Channels	Not Supported	Not Supported
No of Single Ended Channels(muxed with GPIO)	6 + 6	8+8
No of dedicated single Ended Channels	None	2+2
VREFH/VREFL	None	Yes

8.8.1.2 Voltage reference selection (REFSEL settings)

The bit field definition for ADCx_CFG[REFSEL] is as follows for this chip:

00	Selects VREFH/VREFL as reference voltage. VREFH/VREFL are connected to VREFH_ADC and VREFL_ADC pads.
01	Selects VALTH/VALTL as reference voltage. VALTH/VALTL are connected to ADC reference voltage (1.2V) from Voltage Regulator.
10	Selects VBGH/VBGL as reference voltage. VBGH/VBGL are connected to ADC reference voltage (1.2V) from Voltage Regulator. (Same as 01 above).
11	Reserved

8.8.1.3 DMA Support on ADC

Applications may require continuous sampling of ADC (4K samples/sec at minimum) that may have considerable load on CPU. Though using PDB to trigger ADC may reduce some CPU load, ADC need to support DMA for higher performance where ADC is sampled at very high rate or cases were PDB is bypassed. ADC should trigger on-chip DMA (via DMA req) on conversion completion.

8.8.1.4 ADC Channel Assignments

Table 8-23. ADC Channel Assignments

ADC Channel	ADC0	ADC1	Type
0	PAD[8]	PAD[6]	External
1	PAD[9]	PAD[7]	External
2	PAD[22]	PAD[24]	External

Table continues on the next page...

Table 8-23. ADC Channel Assignments (continued)

ADC Channel	ADC0	ADC1	Type
3	PAD[23]	PAD[25]	External
4	PAD[26]	PAD[27]	External
5	PAD[103]	PAD[104]	External
6	PAD[59]	PAD[61]	External
7	PAD[60]	PAD[62]	External
8	Dedicated PAD - ADC0SE8	Dedicated PAD - ADC1SE8	External
9	Dedicated PAD - ADC0SE9	Dedicated PAD - ADC1SE9	External

11	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
12	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
13	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
14	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
15	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
16	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
17	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
18	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
19	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
20	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
21	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
22	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
23	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
24	VSS33_IO_ADC_DAC	VSS33_IO_ADC_DAC	NA
25	VREF from dedicated pad or PMU (select one based on register programming of ADC)	VREF from dedicated pad or PMU (select one based on register programming of ADC)	Internal
26	Temperature Sensor	Temperature Sensor	Internal
27	VREF from PMU	VREF from PMU	Internal
28	HI-Z	HI-Z	NA
29	HI-Z	HI-Z	NA
30	HI-Z	HI-Z	NA
31	HI-Z	HI-Z	NA

8.8.1.5 ADC interconnections

Table 8-24. ADC interconnections

Trigger Module	Trigger	Trigger
ADC	ADC0	ADC0
PDB	Trig0	Trig1
LPTIMER	LPTIMER-Trig	LPTIMER-Trig

8.8.1.6 ADC Calibration

The device fuse map (Bank7-Word5) has been assigned to store the 16-bit calibrated value for ADC0 and ADC1. This calibrated value is derived at room temperature, with nominal voltage and with max averaging. This calibrated value must be copied from Fuses to ADC register to prevent running calibration sequence at reset. Alternatively, calibration sequence supported by ADC may be run after each and every reset and the programmed value in the fuses may be ignored.

8.8.2 12-Bit Digital-to-Analog Converter (DAC)

8.8.2.1 12-bit DAC Instantiation

Table 8-25. 12-bit DAC Instantiation

	176 LQFP	364 BGA
Number of 12-bit DACs	2	2

8.8.2.2 12-bit DAC External Reference

For this device, external voltage supplied to VREFH_ADC pin is the only reference voltage for DAC reference. You need to set up DACx_STATCTRL[DACRFS]=1 to select the valid VREFH_ADC reference. When DACx_STATCTRL[DACRFS]=0, the DAC reference is connected to an internal ground node and is not a valid voltage reference. Be aware that if the DAC and ADC use the VREFH_ADC reference simultaneously,some degradation of ADC accuracy is to be expected due to DAC switching.

8.8.2.3 DMA support on DAC

Applications may require continuous sampling of DAC (4K samples/sec at minimum) that may have considerable load on CPU. The DAC supports DMA for higher performance where the DAC is sampled at a very high rate. To trigger a DMA request, the DAC uses the watermark and buffer bottom and up flags. The DAC must trigger on-chip DMA (via DMA request) on conversion completion.

8.8.2.4 DAC interconnections

Table 8-26. DAC interconnections

DAC trigger from PDB	Connection
DAC0	DAC refresh trigger 0
DAC1	DAC refresh trigger 1

8.9 Display/Video interfaces

8.9.1 Display Control Unit

8.9.1.1 Instantiation

The DCU4 modules connect to the NIC301 as bus masters.

Each DCU4 interface is a 64-bit AXI

Each DCU features an APB interface for control.

HSYNC/VSYNC, DE and Pixel Clock connect to I/O as well as to inputs of a TCON module for generation of additional timing signals

8.9.2 Timing Controller (TCON)

8.9.2.1 Instantiation

Number of TCON instances: 2 (one for each DCU)

Number of timing channels: 12

8.9.3 RLE Decoder (RLE)

8.9.3.1 Instantiation

Number of RLE_DEC instances: 1

Module is disabled by default.

8.9.4 Segmented LCD Controller

8.9.4.1 Instantiation

There is one instance of the LCD module on this device that is connected to the AIPS peripheral bridge.

8.9.4.2 LCD clock selection

The LCD module can be optionally clocked by the system bus clock, the internal 128 KHz IRC or the external 32 KHz crystal clock.

Mode	Description
Normal Run Mode	In normal run modes the LCD is clocked by the system clock.
Low Power Mode	In low power modes of operation to conserve power the LCD module is optionally clocked by the internal 128 KHz IRC or the 32 KHz external crystal oscillator. These two clock sources are available in the low power domains.

8.9.4.3 Segment LCD configuration

In this device the LCD module will be part of the Low Power Domain to enable LCD display content to be maintained. For the display to be updated the MPU must wake up from Low Power mode.

NOTE

The device does not support 5V I/O, therefore the LCD module will interface only to 3.6V glass.

Table 8-28. Number of Front and Back Planes

Parameter	Value
Number of Front Planes	40 or 38 or 36
Number of Back Planes	4 or 6 or 8

NOTE

There are only ten LCDRAM registers (LCDRAM0-LCDRAM9) implemented on this device. The other registers (LCDRAM10-LCDRAM15) that are described in the LCD chapter are not available on this device.

8.9.5 Video Interface Unit(VIU)

8.9.5.1 Instantiation

Number of VIU3 instances: 1

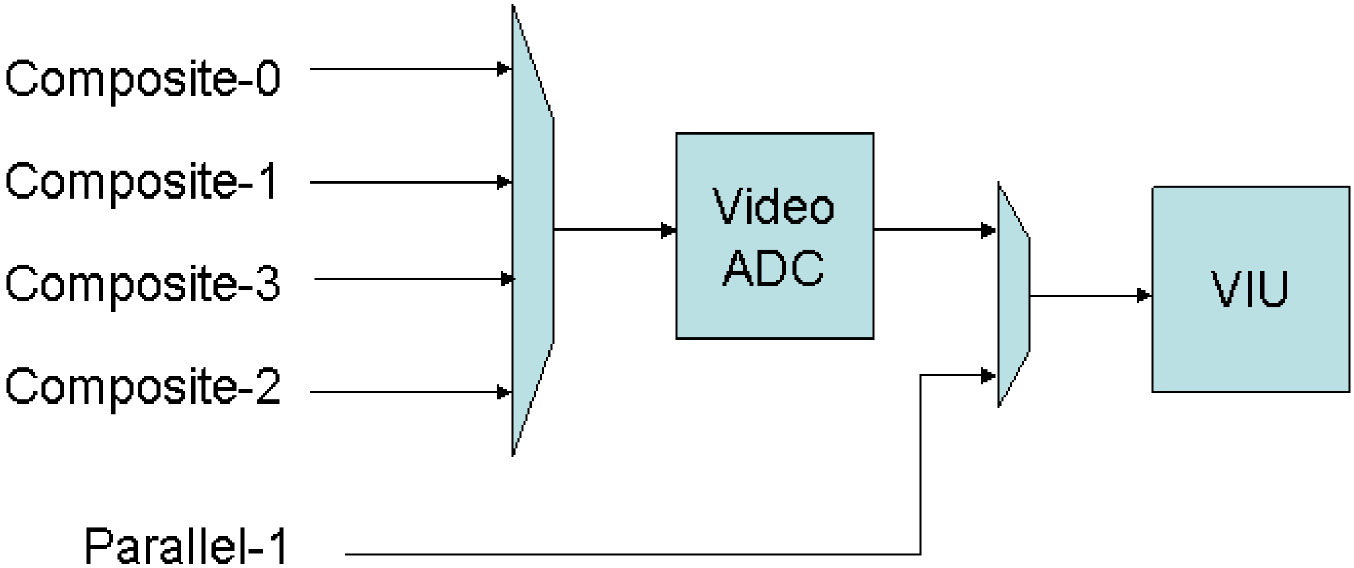
8.9.6 Video ADC(VADC)

8.9.6.1 Instantiation

This device features one instance of the VideoADC

The VideoADC accepts up to 4 single-ended analog inputs.

The VideoADC digital output interfaces directly to the VIU module as shown below.



NOTE

This mux is controlled by the MISC2 register in the SRC module.

8.10 Audio Subsystem

8.10.1 Audio Subsystem Modules

8.10.1.1 Audio Subsystem Overview

The modules that belong to the audio subsystem are the SAI0, SAI1, SAI2, SAI3, ESAI, ESAI_BIFIFO, SPDIF and ASRC. In addition, the IOMUX must be appropriately configured to get signals in and out of the chip.

SAI0-3 are synchronous audio interfaces used to transfer audio data. SAI0-3 are on the peripheral bus.

The ESAI (Enhanced Serial Audio Interface) provides a full-duplex serial port for serial communication with a variety of serial devices, including industry-standard codecs, SPDIF transceivers, and other processors. The ESAI consists of independent transmitter and receiver sections, each section with its own clock generator. The ESAI is connected to the IOMUX and to the ESAI_BIFIFO module.

The ESAI_BIFIFO (ESAI Bus Interface and FIFO) is the interface between the ESAI module and the shared peripheral bus. It contains the FIFOs used to buffer data to/from the ESAI, as well as providing the data word alignment and padding necessary to match the 24-bit data bus of the ESAI to the 32-bit data bus of the shared peripheral bus.

The SPDIF (Sony/Philips Digital Interface) audio module is a stereo transceiver that allows the processor to receive and transmit digital audio over it. The SPDIF receiver section includes a frequency measurement block that allows the precise measurement of an incoming sampling frequency. A recovered clock is provided by the SPDIF receiver section and may be used to drive both internal and external components in the system. The SPDIF is connected to the shared peripheral bus.

The ASRC is a hardware audio sample rate converter supporting up to 10 channels split into 3 sampling rate pairs.

8.10.1.2 Synchronous Audio Interface (SAI)

The Synchronous Audio Interface (SAI) implements supports full-duplex serial interfaces with frame synchronization such as I2S, AC97, and codec/DSP interfaces.

This device implements four SAI modules. SAI0-2 are required for connected radio applications with Radio Tuner devices. SAI3 is added to support future expansion.

The following table shows the configuration of the SAIs:

Table 8-29. SAI Configurations

SAI Instance	Tx Data Lines	Rx Data Lines	Tx FIFO Depth	Rx FIFO Depth
SAI0	1	1	32	32
SAI1	1	1	32	32
SAI2	1	1	32	32
SAI3	1	1	64	64

8.10.1.2.1 SAI3 register details

The dedicated SAI chapter documents the identically instantiated SAI0, SAI1, and SAI2. The following table summarizes SAI3 register details that differ from the other module instances.

Table 8-30. SAI3 register differences from other SAI instances

Instance	TCR1[TFW] and RCR1[RFW]	TFR[WFP], TFR[RFP], RFR[WFP], and RFR[RFP]
SAI3	Each field is 6 bits wide	Each field is 7 bits wide

8.10.1.2.2 Simultaneous SAI DMA requests

If all four instances of the SAI module issue DMA requests simultaneously, DMA must be configured in round robin arbitration mode.

8.10.1.2.3 SAI transmitter and receiver options for MCLK selection

For an internally generated bit clock of the transmitter or receiver, all SAI instances have the same options for selecting an audio master clock (MCLK) source. TCR2[MSEL] and RCR2[MSEL] independently select the MCLK source for the transmitter and receiver, respectively. The following table shows the MSEL settings and the corresponding available MCLK sources on this device.

Table 8-31. SAIn transmitter and receiver options for MCLK selection

TCR2[MSEL] or RCR2[MSEL]	MCLK source for internally generated bit clock of transmitter or receiver
00	Bus Clock
01	Clock selected by CCM_CSCMR1[SAIn_CLK_SEL]
10	Not supported
11	Not supported

8.10.1.2.4 SAI in Stop mode

MCU wakeup from an SAI module is not supported because the SAI clock is gated in Stop mode. Before the MCU enters Stop mode, you must disable operation of the SAI transmitter and receiver in Stop mode. More specifically:

1. In the SAI, program TCSR[STOPE] and RCSR[STOPE] to 0.
2. Execute the MCU's entry to Stop mode.

8.10.1.3 Enhanced Serial Audio Interface (ESAI)

The Enhanced Serial Audio Interface (ESAI) provides a full-duplex serial port for serial communication with a variety of serial devices, including industry-standard codecs, SPDIF transceivers, and other processors.

The ESAI consists of independent transmitter and receiver sections, each section with its own clock generator. All serial transfers are synchronized to a clock. Additional synchronization signals are used to delineate the word frames. The normal mode of operation is used to transfer data at a periodic rate, one word per period. The network mode is also intended for periodic transfers; however, it supports up to 32 words (time

slots) per period. This mode can be used to build time division multiplexed (TDM) networks. In contrast, the on-demand mode is intended for non-periodic transfers of data and to transfer data serially at high speed when the data becomes available.

The ESAI has 12 pins for data and clocking connection to external devices. The ESAI is internally connected to the ESAI_BIFIFO, and does not connect directly to the shared peripheral bus. The ESAI interface is designed for a 24-bit data bus, while the shared peripheral data bus is 32-bit wide. Also, the ESAI data paths are only double buffered, not allowing efficient DMA service in the applications processor environment. The ESAI_BIFIFO allows increasing the data buffering and data width matching to the shared peripheral bus.

8.10.1.4 ESAI Bus Interface and FIFO (ESAI_BIFIFO)

The ESAI_BIFIFO (ESAI Bus Interface and FIFO) is the interface between the ESAI module and the shared peripheral bus. It contains the FIFOs used to buffer data to/from the ESAI, as well as providing the data word alignment and padding necessary to match the 24-bit data bus of the ESAI to the 32-bit data bus of the shared peripheral bus..

There are two independent 128-word FIFOs, one servicing the ESAI transmit section, shared by the 6 ESAI transmitters, while the other 128-word FIFO services the ESAI receive section, shared by the 4 ESAI receivers. Each FIFO has a programmable watermark level where it can trigger a DMA service request.

The ESAI 24-bit data words are aligned and formatted according to the Transmit Word Alignment and Receive Word Alignment controls.

8.11 Miscellaneous

8.11.1 GPIO

8.11.1.1 GPIO Mapping

Table 8-32. RGPIO versus Pins

RGPIO	In GPIO module	Corresponding Pin on the chip	IOMUX register name	IOMUX register address
RGPIO[0]	PORT0[0]	PTA6	IOMUXC_PTA6	40048000
RGPIO[1]	PORT0[1]	PTA8	IOMUXC_PTA8	40048004
RGPIO[2]	PORT0[2]	PTA9	IOMUXC_PTA9	40048008

8.11.1.2 Configuring a pin as GPIO

To program a pin as GPIO:

1. Program the corresponding register in IOMUX. For example, to configure PORT0-pin16 (PTA16), program IOMUXC_PTA16.
2. Program proper ALT mode in this register and program IBE (for Input) and OBE (for Output).
3. Program the GPIO registers (PDOR, PSOR, PCOR, PTOR, PDIR) you can set/reset this pin or read from this pin.

NOTE

For details about IOMUX and GPIO registers, see the respective chapters of this document.

8.11.1.3 Port 4 Register Differences

In this device, 135 PADs are implemented across 5 RGPIO port instances as 4 x 32 + 7. The last instance has only 7 PAD control registers. The dedicated RGPIO chapter documents the identically instantiated Port 0, 1, 2, and 3. The following table summarizes Port E register details that differ from the other module instances.

Table 8-33. Port 4 register differences from other Port instances

Instance	Port Data Output Register (GPIO_PDOR)	Port Data Input Register (GPIO_PDIR)
Port 4	PDO[6:0] field is 7 bits wide	PDI [6:0] field is 7 bits wide

Chapter 9
Clocking Overview

9.1 Introduction

The clocking on this device is flexible and allows clock from multiple sources to be used across different IPs and peripherals. Clocks on the device are controlled by ANADIG, SCSC and CCM modules. All clock sources lead to the CCM module, which generates the root clocks for the bus and peripherals of the device. The control logic in CCM additionally generates special clocks for peripherals which run asynchronously to the root clock and are termed as Auxiliary clocks. This chapter provides a top level description of the clock sources and their arrangement.

Read the following chapters in conjunction with this chapter for the respective details.

- CCM - To program the selection of clock sources, refer to the registers in Clock Controller Module (CCM) chapter. CCM also controls clock gating on this device.
- ANADIG - To program the PLLs and PFDs configuration, refer to the registers in ANADIG chapter.
- SCSC - To configure SIRC and SOSC controls, refer to the registers in SCSC chapter.

9.2 High Level Clocking Diagram

The figure below provides an overview of system clock generation on this device.

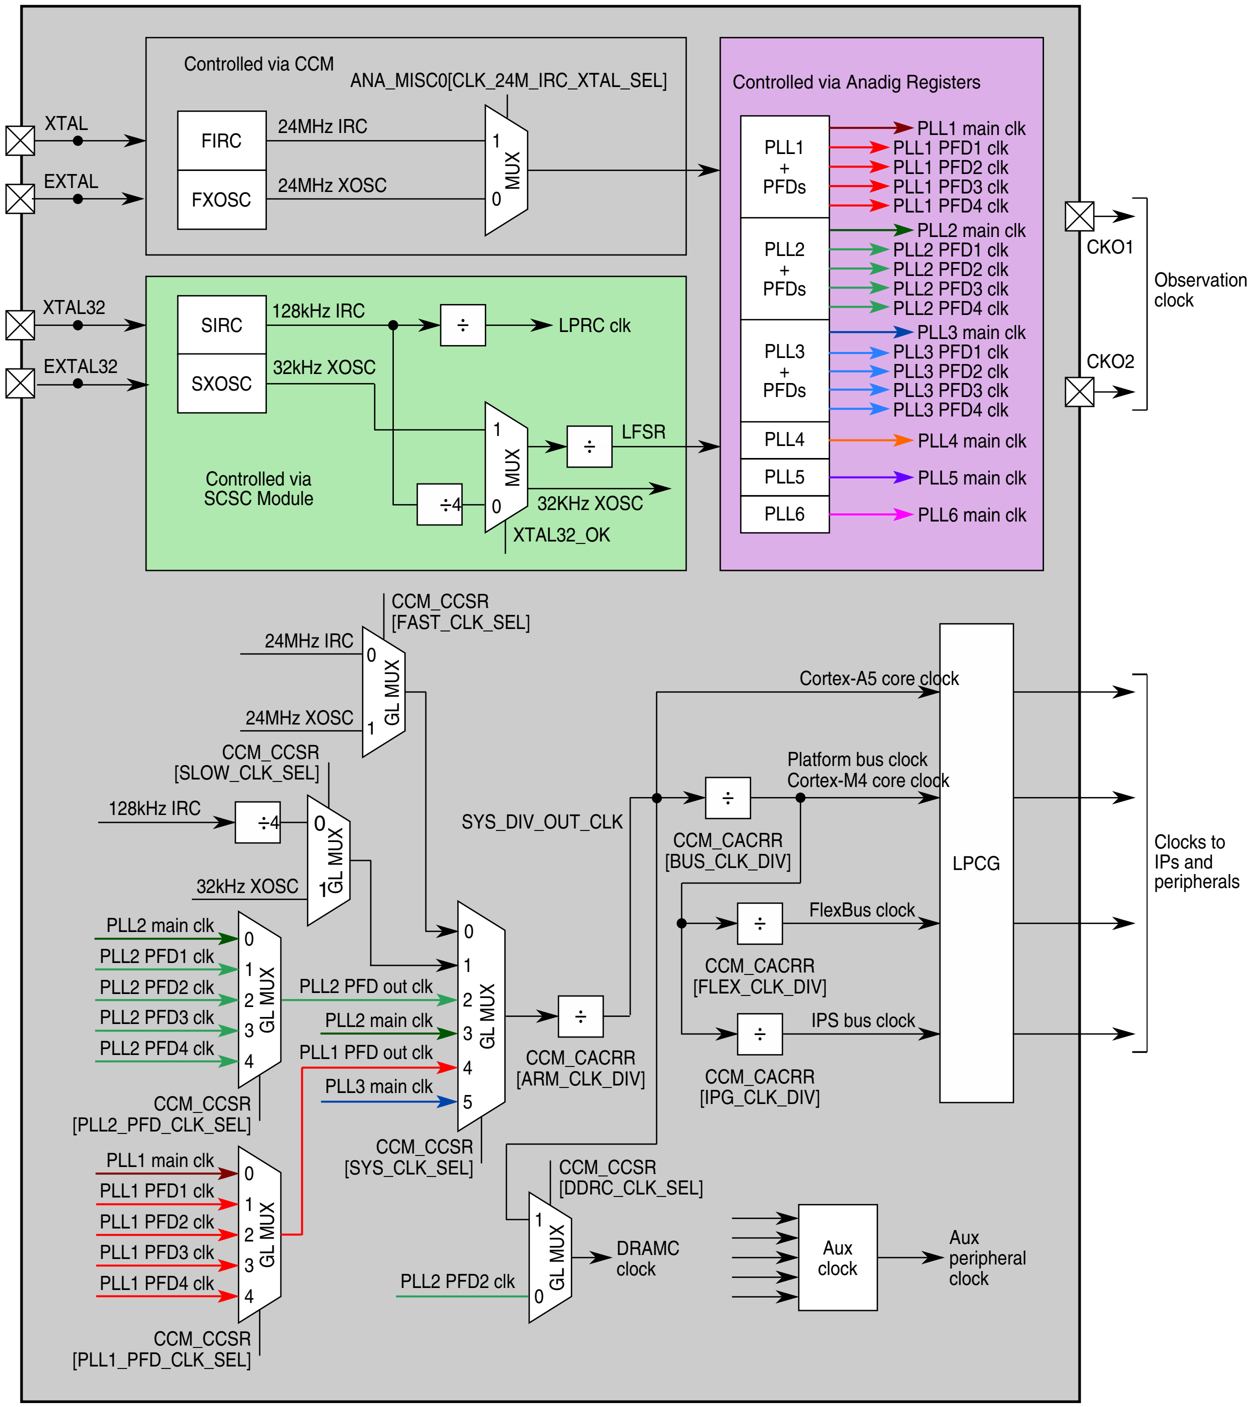

Figure 9-1. Clock Generation and Distribution

NOTE

XTAL32_OK is an internal signal signifying availability of the SXOSC clock. If the external 32 KHz XOSC signal is not available, SIRC/4 is used instead.

NOTE

LPRC CLK - 1KHz clock that can be used by LPTMR counter.

The table below defines the clocks on the device.

Table 9-1. Clock Definitions

Clock	Definition
Platform Bus/Cortex-M4 Clock[1]	Cortex-M4, Network interconnect (NIC301), and the host bus interfaces of different IPs operate on this clock.
Cortex-A5 Core clock	Cortex-A5 core clock
IPS Clock	This is the register read/write interface clock for any IP and it is a gated version of the IPG clock automatically enabled when accessing the register interface. This clock is active only during register access.
IPG Bus Clock	IPG clock is half the frequency of platform bus clock. Internal engines for IPs work on this clock. Program CCM_CACRR[IPG_CLK_DIV] to 01.
Auxillary Clock	Asynchronous clocks required by individual IPs.
LFSR Clock	Divided SXOSC clock for tamper detection. Refer to Security Architecture for details.
LPRC Clock	1 KHz clock that can be used by LPTMR counter. Refer to LPTMR_PSR register in the LPTMR chapter for details.

1. Platform Bus/Cortex-M4 Clock, Cortex-A5 Core Clock, IPS Bus clock, and IPG Bus Clock are synchronus to each other.

9.3 Clock Sources

The device implements seven PLLs and four oscillators to meet the clocking requirements of the system. Some PLL outputs are fixed, while others are configurable. Three of the PLLs have further supplemented with PFD (Phase Frequency Dividers) support, which generate independent clock frequencies using the VCO frequency generated by the PLLs. These PFD outputs can then be selected to clock the system and various modules.

In addition to the PLLs, the device also includes:

- 2 external crystal oscillators (XOSC)
    - Fast external crystal oscillator 24 MHz (FXOSC)
    - Slow external crystal oscillator 32 KHz (SXOSC)
- 2 internal RC (IRC) oscillators
    - Fast internal RC oscillator 24 MHz (FIRC)
    - Slow internal RC oscillator 128 KHz (SIRC)

NOTE

FXOSC/FIRC clocks are configured by the CCM module. SXOSC/SIRC clocks are configured by the SCSC module.

NOTE

If the external 32KHz XOSC signal is not available, the chip will automatically use the SIRC/4 clock to provide a 32KHz clock, provided the SIRC is not disabled by software.

9.4 PLL Summary

9.4.1 PLL Block DIAGRAM

The figure below provides an overview of PLL and PFD controls on this device. Only three of the PLLs have a corresponding PFD.

NOTE

PLL and PFD controls are programmed via ANADIG registers. The table below maps the bits/fields of ANADIG Registers to the figure below.

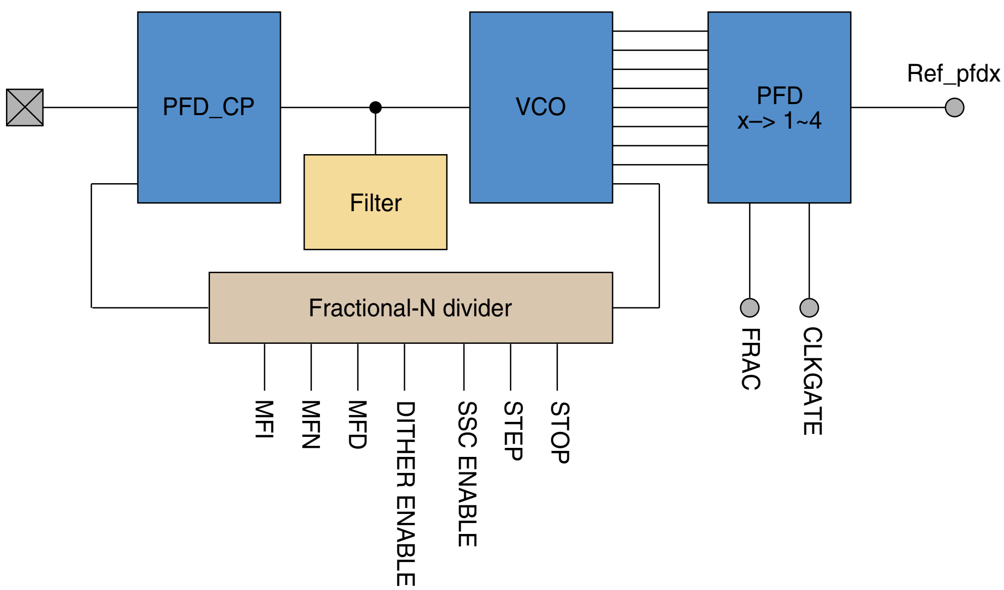

Figure 9-2. PLL Block Diagram

Primary Fractional Divider (PFD) — Each PFD works independently by interpolating the VCO of the PLL it is connected to. It takes the PLL VCO frequency and produces 18/N*Fvco its PFD output, where N ranges from 12 to 35. The time to switch frequencies is

much faster than a PLL, as the base PLL stays locked and changing the integer N just changes logical combination that controls the PFD output. These PFD outputs can be used by the system clocks or modules.

MFI	Controlled via DIV_SELECT field of ANADIG PLL Control registers
MFN	Controlled via ANADIG PLL2 Numerator definition register, ANADIG PLL1 Numerator definition register, ANADIG PLL4 Numerator definition register, ANADIG PLL6 Numerator definition register
MFD	Controlled via ANADIG PLL2 Denominator definition register, ANADIG PLL4 Denominator definition registerANADIG PLL6 Denominator definition register
STEP	Controlled via STEP field of ANADIG PLL2 Spread Spectrum definition register and PLL1 Spread Spectrum definition register
STOP	Controlled via STOP field of ANADIG PLL2 Spread Spectrum definition register and PLL1 Spread Spectrum definition register
SSC ENABLE	Controlled via ENABLE field of ANADIG PLL2 Spread Spectrum definition register and PLL1 Spread Spectrum definition register
DITHER ENABLE	Contfrolled via ANADIG PLL2 Control register, ANADIG PLL4 Control register, ANADIG PLL6 Control register, Anadig PLL5 Control register, and ANADIG PLL1 Control register
FRAC	Controlled via PFD1_FRAC, PFD2_FRAC, PFD3_FRAC, PFD3_FRAC, PFD4_FRAC fields of ANADIG_PLL3_PFD definition, ANADIG_PLL2_PFD, and ANADIG_PLL1_PFD register
CLKGATE	Controlled via PFD1_CLKGATE, PFD2_CLKGATE, PFD3_CLKGATE, PFD4_CLKGATE bits of ANADIG_PLL3_PFD definition, ANADIG_PLL2_PFD, and ANADIG_PLL1_PFD register

9.4.2 Spread Spectrum (SSC)

PLL1 and PLL2 support the Spread Spectrum (SSC) on its output. In SSC mode, the recommended modulation frequency is 30 KHz and 2% (peak-peak) frequency spread is supported. Using the equations below, the appropriate values of STOP and STEP can be derived. It is important to note that only Down spread frequency modulation is supported.

$$\text{Spread Spectrum Range} = F_{ref} * \left(\frac{STOP}{MFD}\right)$$

$$\text{Modulation Frequency} = F_{ref} * \left(\frac{STEP}{2*STOP}\right)$$

NOTE

"Spread Spectrum Range" is in Hz.

Example: To add 2% spread at 30kHz on default PLL1, the PLL1 MFD could be set to 10000 (this would not affect output as MFN = 0). The spread spectrum range would be 2% of 528MHz. From this we can work out that STOP should be set to 4400.

Using the recommended modulation frequency of 30kHz, the STEP value can be worked out to be 11.

F0 = Fref * N Where, N = Total Loop Division (Integer + Fraction)

PLL output frequency variation with a 2% modulation is shown in the figure below.

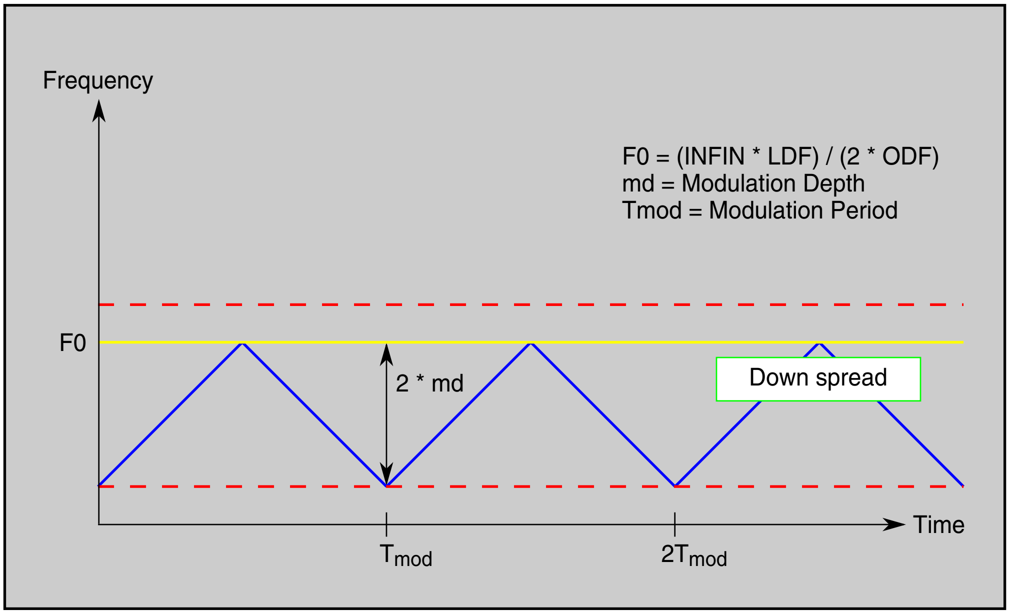

Figure 9-3. PLL with 2% Frequency Down spread Modulation

9.4.3 PLL Summary

The table below describes the properties of PLLs on this device.

Table 9-2. PLL Properties

		Basic			Spread Spectrum Support	PFD Output	Comments
PLL	**Description**	**Control**	**MFD**	**MFN**	**Available**	**Available**	**Comments**
PLL1 (PLLSYS 528 MHz)	This is a system PLL that generates the ARM subsystem clock.	Configurable DITHER and MFI	Configurable	Configurable	Yes	4	-
PLL2 (PLL 528 MHz)	This generates the PLL for DDR operation, as well as other modules.	Configurable DITHER and MFI	Configurable	Configurable	Yes	4	
PLL3 (USB0 PLL)	This generates a 480MHz clock to be used for USB0 and other modules.	Configurable DITHER. Fixed MFI.	NA (Fixed)	NA (Fixed)	NO	4	VCO output is fixed at 480 MHz, with MFI set to 20
PLL4 (Audio PLL)	This is a fractional multiplier PLL for generating Audio frequencies.	Configurable DITHER and MFI	Configurable	Configurable	NO	None	
PLL5 (ENET PLL)[1]	This PLL is used to generate 50 or 25 MHz for the external Ethernet interface.	Configurable DITHER and MFI	NA (Fixed)	NA (Fixed)	NO	None	VCO Output fixed at 1000 MHz
PLL6 (Video PLL)	This is a fractional multiplier PLL for generating Video frequencies.	Configurable DITHER and MFI	Configurable	Configurable	NO	None	

Table continues on the next page...

Table 9-2. PLL Properties (continued)

		Basic			Spread Spectrum Support	PFD Output	Comments
PLL	Description	Control	MFD	MFN	Available	Available	Comments
PLL 7 (USB1 PLL)	This generates a 480 MHz clock to be used for USB1.	No DITHER. Fixed MFI.	NA (Fixed)	NA (Fixed)	NO	None	

1. USB1 PHY has a separate internal PLL, PLL7 generating 480 MHz, from the 24 MHz FXOSC. This PLL is only used by USB1 PHY and does not have any PFDs

9.5 PLL Features

9.5.1 528 MHz Phase Locked Loop

Features:

- Synthesizes low jitter clock from 24MHz reference clock.
- Nine phase outputs of 528 MHz, plus 4 PFDs.
- Spread Spectrum support
- 2.5V ±10% Analog supply. 1.1V ±10% digital supply

$$\text{PLL Output Frequency} = F_{\text{ref}} * \left(\text{MFI} + \frac{\text{MFN}}{\text{MFD}}\right)$$

In the above equation:

- MFI - Multiplication Factor Integer (ANADIG_PLLx_CTRL[DIV_SELECT])
- MFN - Multiplication Factor Numerator (ANADIG_PLLx_NUM)
- MFD - Multiplication Factor Denominator (ANADIG_PLLx_DENOM)

$$\text{Spread Spectrum Range} = F_{\text{ref}} * \left(\frac{\text{STOP}}{\text{MFD}}\right)$$

$$\text{Modulation Frequency} = F_{\text{ref}} * \left(\frac{\text{STEP}}{2*\text{STOP}}\right)$$

$$\text{PFDn Output Frequency} = \text{PLLx Output Frequency} * \left(\frac{18}{\text{PFDn\_FRAC}}\right)$$

MFD is in ANADIG_PLLx_DENOM STEP and STOP are in ANADIG_PLLx_SS PFDn_FRAC is in ANADIG_PLLx_PFD[PFDn_FRAC]

For the electrical specifications, refer to the device Data Sheet.

NOTE

Registers that contain the configuration fields for the variables in the equations above for the 528 MHz PLLs are described in the ANADIG Registers chapter in this manual.

9.5.2 High Frequency PLL

There are two instances of this PLL:

- PLL4 - Used for audio clock generation
- PLL6 - Used for video clock generation

Features:

- Synthesizes low jitter clock from 24 MHz reference clock
- Clock output frequency range is from 650 MHz to 1.3 GHz
- Fractional-N synthesizer
- 2.5 V+-10% Analog supply. 1.1 V+-10% digital supply

PLL Output frequency is calculated based on the below equations:

$$\text{PLL Output Frequency} = F_{\text{ref}} * \left(\text{MFI} + \frac{\text{MFN}}{\text{MFD}}\right)$$

In the above equation:

- MFI - Multiplication Factor Integer (ANADIG_PLLx_CTRL[DIV_SELECT])
- MFN - Multiplication Factor Numerator (ANADIG_PLLx_NUM)
- MFD - Multiplication Factor Denominator (ANADIG_PLLx_DENOM)

$$\text{Modulation Frequency} = F_{\text{ref}} * \left(\frac{\text{STEP}}{2*\text{STOP}}\right)$$

Recommended modulation frequency is 30KHz. STEP and STOP are set in the ANADIG_PLLx_SS register.

For the Audio/Video PLL electrical specifications, refer to the device Data Sheet.

NOTE

Registers that contain the configuration fields for the variables in the equations above for the for Audio/Video PLLs described in the Anadig Registers chapter in this manual.

9.5.3 Ethernet PLL

Features:

- Synthesizes low jitter clock from 24 MHz reference clock.

- VCO OSC frequency = 1000 MHz / 2
- Outputs:
  - Programmable divider - 25/50/100 (ENET reference)

NOTE

Registers that contain the configuration fields for the variables in the equations above for the Ethernet PLL are described in the ANADIG Registers chapter in this manual. Some variables are fixed and are not available in the registers.

For the electrical specifications, refer to the device Data Sheet.

$$\text{PLL Output Frequency} = F_{ref} * \left(MFI + \frac{MFN}{MFD}\right)$$

Where:

- MFI: Multiplication Factor Integer
- MFN: Multiplication Factor Numerator
- MFD: Multiplication Factor Denominator

9.6 PLL/PFD Configuration

9.6.1 PLL Configuration

9.6.1.1 Typical PLL Configuration

Table 9-3. Typical PLL Configurations

Name	MFI	MFN	MFD	PFD	PFD Setting	Output (MHz)
PLL1 (PLLSYS)	ANADIG_PLL1_CTRL[DIV_SELECT]=1	0x0	0x12	PFD1	‘d19 (0x13)	500
				PFD2	‘d21 (0x15)	452
				PFD3	‘d24 (0x18)	396
				PFD4	‘d18 (0x12)	528
PLL2 (PLL528)	ANADIG_PLL2_CTRL[DIV_SELECT]=1 (24*22=528 MHz)	0x0	0x12	PFD1	‘d19 (0x13)	500
				PFD2	‘d24 (0x18)	396
				PFD3	‘d28 (0x1C)	339
				PFD4	‘d23 (0x17)	413

Table continues on the next page...

Table 9-3. Typical PLL Configurations (continued)

Name	MFI	MFN	MFD	PFD	PFD Setting	Output (MHz)
PLL 3 (USB0 PLL)	ANADIG_PLL3_CTRL[DIV_SELECT]=0 (24*20=480 MHz)			PFD1	'd28 (0x1C)	Actual o/p 308 MHz
				PFD2	‘d26 (0x1A)	332 MHz
				PFD3	‘d29 (0x1D)/ ’d28 (0x1C)	298 MHz/ 309 MHz
				PFD4	'd27 (0x1B)	320 MHz
PLL4 (Audio PLL) (default)	0x31	0x04DD2F15	0x1FFFFFDB	PLL Output = 24*49.152=1179.648 MHz **NOTE:** This when divided by 48 generates 512x48KHz		
PLL4 (other use case)	0x2F	0x0147AE13	0x1FFFFFDB	PLL output = 24*47.02=1128.48 MHz **NOTE:** This when divided by 50 generates 512x44.1KHz		
PLL5 (ENET PLL)	0x29 (tied internally)	0xAAAAD44 (tied internally)	0x100003E6 (tied internally)	VCO Clock = 24*41.66=1000, internally divided by 2 generates 500 MHz, **NOTE:** ANADIG_PLL5_CTRL[DIV_SELECT]=0x1 generates 50 MHz clock output.		
PLL6 (Video PLL)	0x2C	0xAAAAA9E	0x1FFFFFDA	PLL output = 24M*44.33=1064 MHz **NOTE:** This when divided by 8 generates 133 MHz		
PLL6 (default)	0x28	0x0	0x12	PLL output = 24*40=960 MHz **NOTE:** This when divided by 8 generates 120 MHz		
PLL7 (USB1 PLL)	ANADIG_PLL7_CTRL[DIV_SELECT]=0 (24*20=480 MHz)					

9.6.2 PFD Configuration

9.6.2.1 Typical PFD Configuration

Table 9-4. Typical PFD Configuration

PLL	PFD	Frequency	Notes
PLL1	PFD1	500	-
	PFD2	452	For Cortex-A5 clock
	PFD3	396	Synchronous Cortex-A5
	PFD4	528	To generate x4 clock of 264 MHz for QSPI in DDR66 mode

Table continues on the next page...

Table 9-4. Typical PFD Configuration (continued)

PLL	PFD	Frequency	Notes
PLL2	PFD1	500	Reserved
	PFD2	396	For DDR operation
	PFD3	339	For 339:166 synchronous DDR operation
	PFD4	413	For QSPI SDR 104 clock. Can also be used for GCC
PLL3	PFD1	308	Reserved for Audio clocking
	PFD2	332	-
	PFD3	298	Reserved for SDHC clocking. In case the above PFD1 is consumed in audio then we switch to PFD3
	PFD4	320	For QSPIx4 for DDR80. 320 MHz clk source requires setting of PFD4_Frac field in ANADIG_PLL3_PFD to 0x1b to allow DDR80 QuadSPI operation.

9.7 Clock Configuration

The table below provides the maximum frequencies of the listed peripherals on this device.

Table 9-5. Clocking Configuration

Clocks	Maximum Frequency
Cortex-A5 Core Clock[1]	500 MHz
Cortex-A5 Core Clock	166 MHz
DDR Clock[2]	400 MHz[3]
Platform Bus or Cortex-M4 Clock	166 MHz
IPS or IPG Clock. This is derived from (Platform Bus or Cortex-M4 Clock)/CCM_CACRR[IPG_CLK_DIV]. Typical value for this divider is 2.	83 MHz
DCU Pixel Clock	from 5 - 60 MHz
SDHC Clock	50 MHz
Video ADC (V_CLK1)	133 MHz
Ethernet (RMII_CLK)	50 MHz
Audio	24.58 MHz

1. Cortex-A5 core clock has to be synchronous to rest of the system.
2. DDR can be synchronous or asynchronous with a maximum speed of 400MHz.
3. Minimum frequency of DDR is 300 MHz

NOTE

On this device, the modules listed below have the register interface working at the same frequency as Platform Bus clock.

- DCU0
- DCU1
- DMA_CH_MUX0
- DMA_CH_MUX1
- DMA_CH_MUX2
- DMA_CH_MUX3
- RLE
- SAI0
- SAI1
- SAI2
- SAI3
- SPDIF
- GCC
- TCON

For other modules on this device, the register interface work at the IPS clock frequency, which is half of Platform Bus clock. For example:

- DAC
- PDB
- PIT
- LPTMR
- SPI
- I2C
- UART
- LCD
- VIU

9.8 Clock Modes

9.8.1 Synchronous Mode

9.8.1.1 Synchronous Mode

In this mode, Cortex-A5, BUS, Cortex-M4, and DDR clocks are synchronous to each other.

In the synchronous mode, all clocks are on the same source and have an integral ratio.

Table 9-6. Synchronous Mode

PFD Selected (Frequency)	Cortex-A5	DDR	BUS/Cortex-M4	IPG	Div Configurations
PLL1->PFD3 or PLL2->PFD2 (396MHz)	396	396	132	66	ARM_DIV = 1 BUS_DIV = 3 IPG_DIV = 2
PLL2->PFD3 (339Mhz)	339	339	169.5	84.75	ARM_DIV = 1 BUS_DIV = 2 IPG_DIV = 2
PLL1->PFD4 (528Mhz)	264	264	132	66	ARM_DIV = 2 BUS_DIV = 2 IPG_DIV = 2
PLL1->PFD1 or PLL2->PFD2 (500Mhz)	250	250	125	62.5	ARM_DIV = 2 BUS_DIV = 2 IPG_DIV = 2

9.8.2 Asynchronous Mode

9.8.2.1 Asynchronous DDR mode

In this mode, Cortex-A5, BUS, Cortex-M4 are synchronous and DDR clock is asynchronous.

In the asynchronous mode, DDR can be operated on different clock source for 400 MHz and Cortex-A5 can go up to 500 MHz. To set up the DDR asynchronous mode, DDR register configuration needs to be done. Refer to DDR Control Registers 117 .

Table 9-7. Asynchronous DDR mode

PFD Used	Cortex-A5	DDR	BUS/Cortex-M4	IPG	Div Configurations
PLL2->PFD3 (339Mhz)	339	396	169.5	84.75	• ARM_DIV = 1 • BUS_DIV = 2 • IPG_DIV = 2
PLL1->PFD2 (452Mhz)	452	396	150.66	75.33	• ARM_DIV = 1 • BUS_DIV = 3 • IPG_DIV =2

9.9 Clock Gating

9.9.1 Clock Gating

The device implements clock gating options for multiple peripherals to save power. The central clock gating is controlled through configuration of CCM Clock Gating Register (CCM_CCGCR) registers for off-platform modules and CCM Platform Clock Gating Register (CCM_CPGCR) for on platform modules. See the CCM chapter for details.

- All the on-platform module clocks are enabled by default.
- All the off-platform module clocks are disabled by default.
- Only CCM and SRC can be accessed without any IPS configuration.
- All auxillary clocks are implemented using asynchronous clock muxes. To avoid any glitch at the output, select the clock source and then enable the clock gating.

NOTE

A transfer error is observed if an access is made to a module that does not have a clock enabled.

NOTE

The Low Power Clock Gating module further gates the clock to various peripherals.

9.10 Peripheral Clocks

9.10.1 Module clocks

The following table summarizes the clocks associated with each module.

Table 9-8. Module clocks

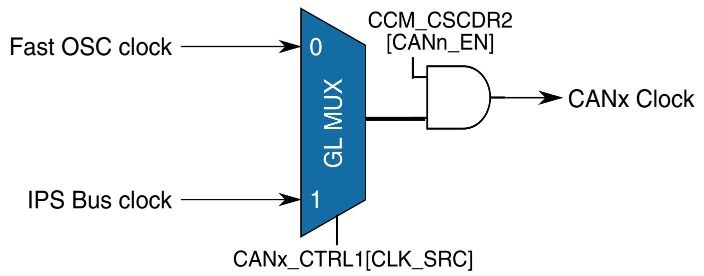
Modules	AHB	IPG Bus Clock	IPS Clock	Relation b/w IPG and IPS	RAM	Baud	Spl care on baud	Any other alternate	Comments
FlexRay	Yes	-	-	-	-	-	-	-	-
ENET_DPRAM	85	85	42.5	-	170	Auxiliary	mii_clk = 100, RMII = 50MHz	-	IPG clock > 50MHz to support both MII/RMII
DMA	SYS/AHB	-	-	-	85	No	-	-	-

Table continues on the next page...

Table 9-8. Module clocks (continued)

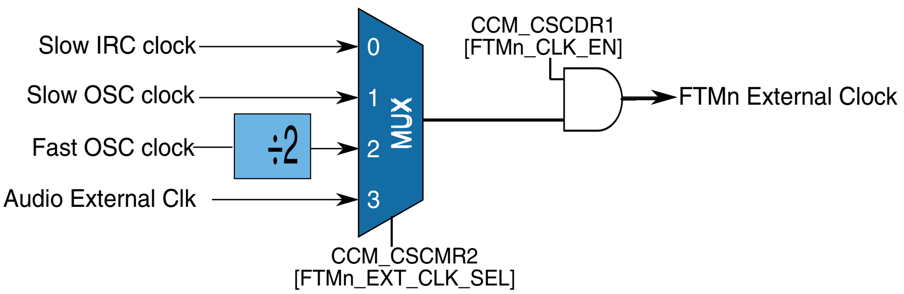
Modules	AHB	IPG Bus Clock	IPS Clock	Relation b/w IPG and IPS	RAM	Baud	Spl care on baud	Any other alternate	Comments
USB	85	-	-	-	85	-	-	-	-
SSCM	No	-	-	-	-	-	-	-	-
wkpu	No	-	-	-	-	-	-	-	-
I2C fil	No	-	-	-	-	-	-	-	-
CMU	No	-	-	-	-	-	-	-	-

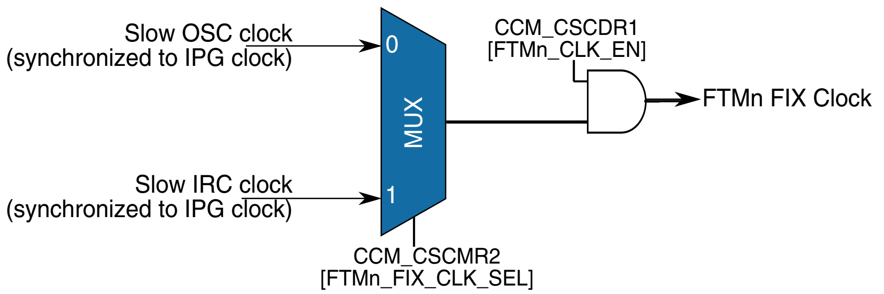
9.10.2 FlexCAN Clocking



9.10.3 FTM clocking

This section shows FlexTimer clocking.

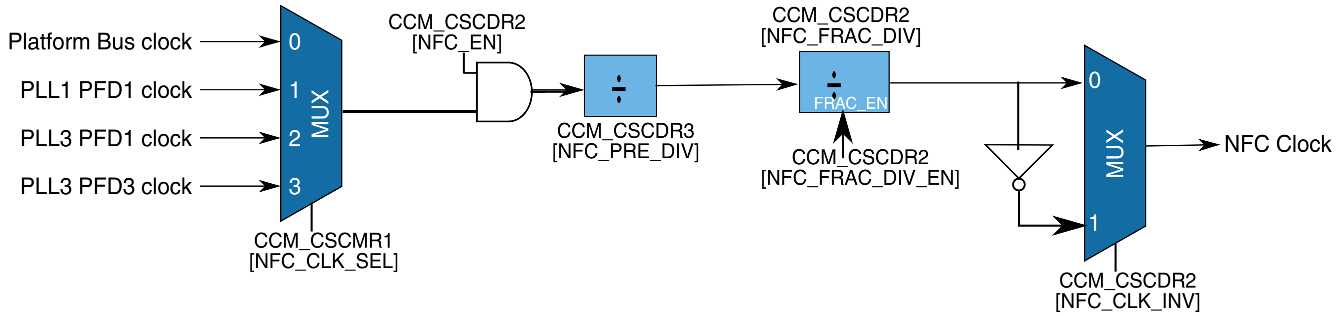




For the clock signal description, refer to the CCM chapter.

9.10.4 NFC clocking

This section shows NAND Flash Controller (NFC) clocking.



For the clock signal description, refer to the Clock Controller Module (CCM) chapter

9.10.5 QuadSPI Clocking

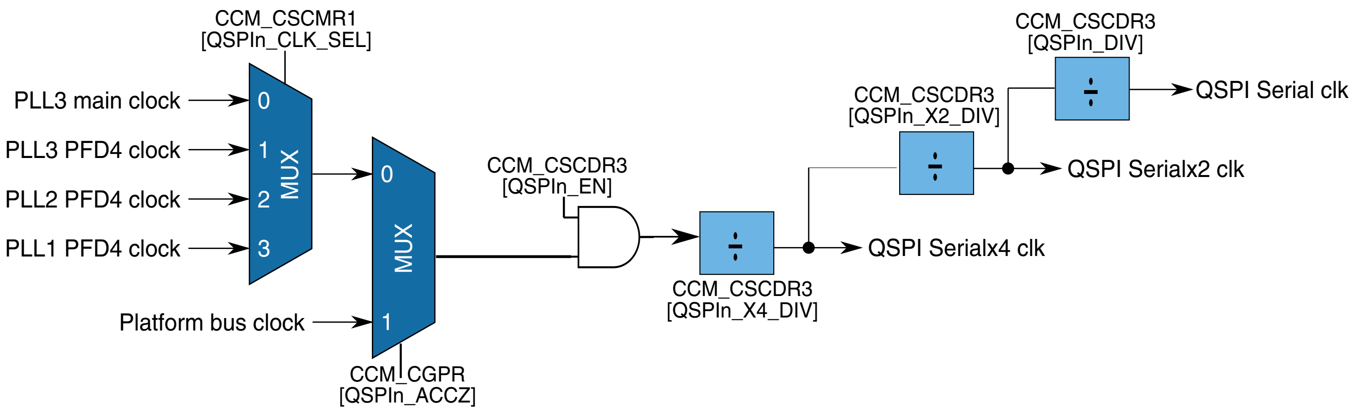


Figure 9-4. QuadSPI Clocking

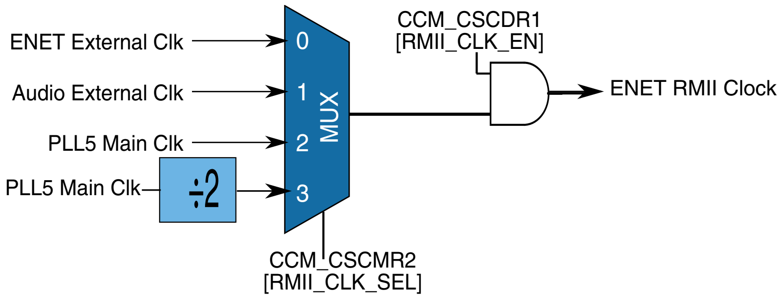
Serial Flash Speed	QuadSPI Clock Requirements	PLL Option	Serialx4 Clk	Serialx2 Clk	Serial Clk
104 MHz SDR	104 MHz	ANADIG_PLL2_PFD[PFD4_FRAC]='d 23 (413MHz)		Not required	104 MHz
66 MHz DDR	132 MHz/264 MHz	ANADIG_PLL1_PFD[PFD4_FRAC]='d 18 (528MHz)	264 MHz	132 MHz	Yes
80 MHz DDR	160 MHz/320 MHz	ANADIG_PLL3_PFD[PFD4_FRAC]='d 27 (320MHz)	320 MHz	160 MHz	Yes

9.10.6 Ethernet RMII/MII Clocking

This section shows Ethernet RMII Clocking.

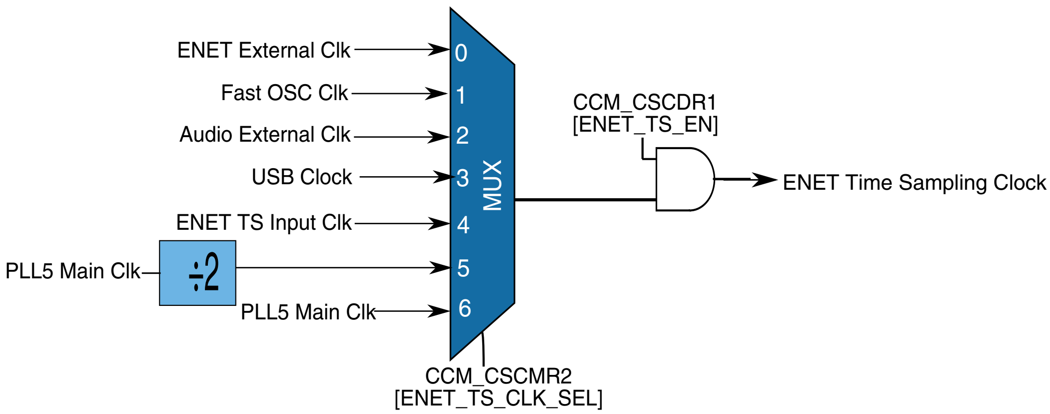


NOTE

When Ethernet MII clocking is used RMII clocking cannot be used. Ethernet MII TXClk is driven by ENET External Clk (PTA6/PTA9) and Ethernet MII RXClk is driven by PTA21.

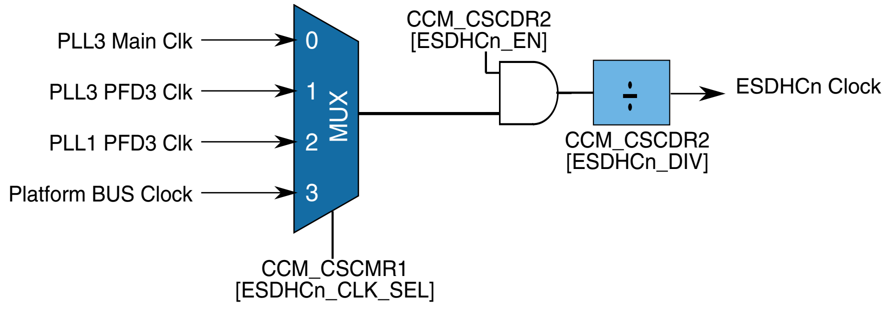
9.10.7 Ethernet Timer Clocking

This section shows Ethernet Timer clocking.



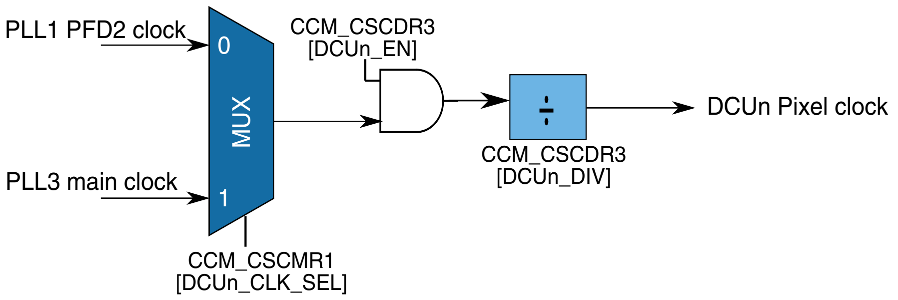
9.10.8 eSDHC Clocking

This section shows eSDHC clocking.



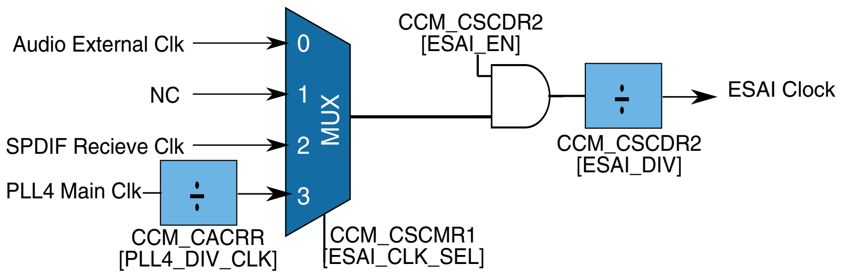
9.10.9 DCU clocking

This section shows DCU clocking.



9.10.10 ESAI clocking

This section shows ESAI clocking.

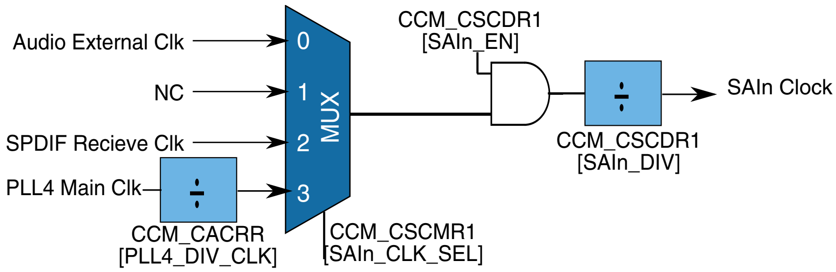


9.10.11 SPDIF Clocking

SPDIF clocking is controlled from the SPDIF module itself, through SPDIF_STC[TxClk_Source]. CCM has no direct control of SPDIF clock. SPDIF clock can be observed through CCM Clock Output Source Register (CCM_CCOSR).

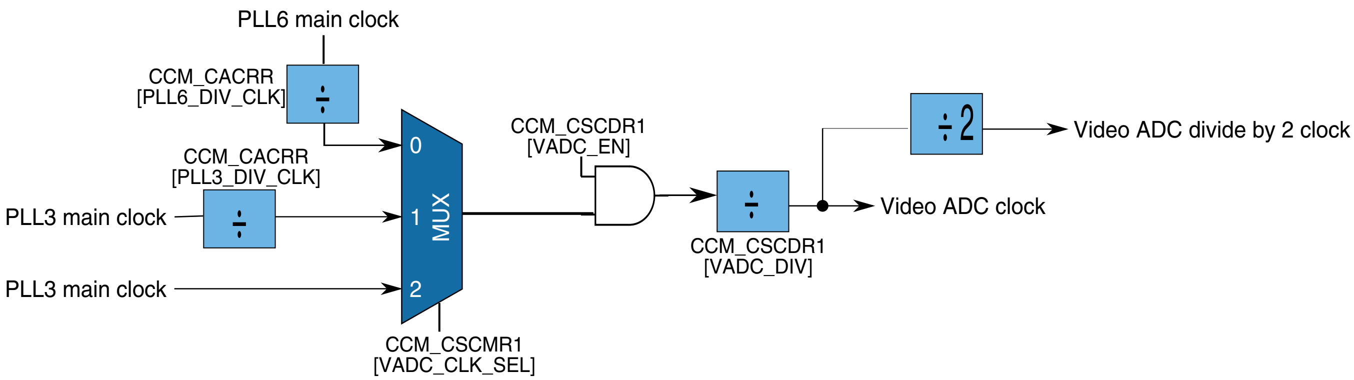
9.10.12 SAI clocking

This section shows SAI clocking.

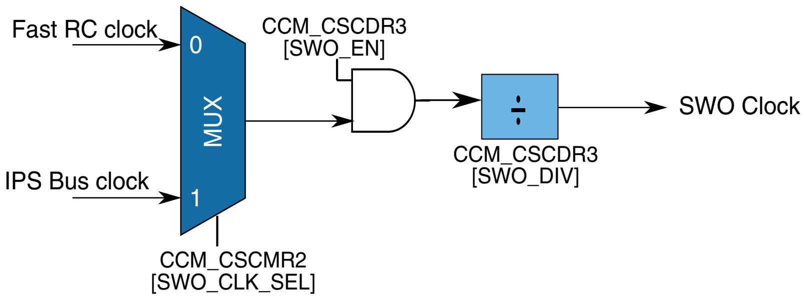


9.10.13 Video ADC clock

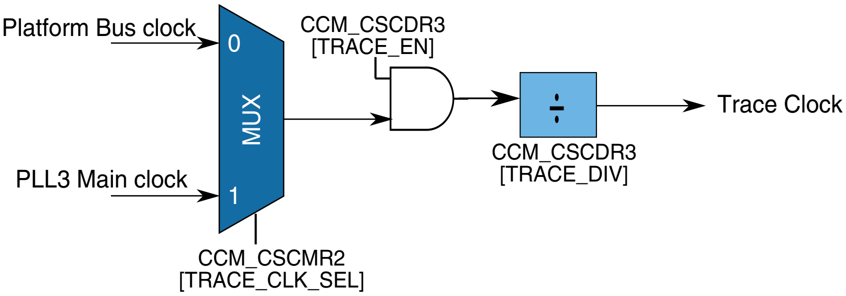
This section shows Video ADC clock.



9.10.14 SWO Clocking



9.10.15 Trace clocking



9.11 Appendix

9.12 Maximum Frequencies Supported

NOTE

Do not configure CCM to generate frequencies higher than those listed n the table below.

Table 9-10. Maximum frequencies

Clock name	Output/Input	Frequency (MHz)	Notes
Platform Bus Clock	output	170	
Cortex-A5 Clock	output	500	
FlexCAN Clock	output	85	
Cortex-M4 Clock	output	170	
DAP Clock	output	170	
DCU Pixel Clock	output	240	When pix_div is to be confirmed at 45/90, CCM should give out 90 MHz
DDRC Clock	output	400	
ENET Clock	input	50	
ENET RMII Clock	output	50	PLL5
ENET MII TX/RX Clock	input	25	
ENET TS Clock	input	100	
ENET Clock	output	50	
eSDHC Clock	output	52	PLL3_PFD3 (Divider inside CCM at 480 MHz)
flex_root_clk	output	85	
1588 TIMER Clock	output	100	PLL5

Table continues on the next page...

Table 9-10. Maximum frequencies (continued)

Clock name	Output/Input	Frequency (MHz)	Notes
IPG	output	85	
NFC Clock	output	80	
PLL1 Main Clock	input	528	
PLL1 PFD1 Clock	input	500	NFC Flash40
PLL1 PFD2 Clock	input	452	
PLL1 PFD3 Clock	input	396	
PLL1 PFD4 Clock	input	528	
PLL2 Main Clock	input	528	
PLL2 PFD1 Clock	input	500	
PLL2 PFD2 Clock	input	396	
PLL2 PFD3 Clock	input	339	
PLL2 PFD4 Clock	input	413	
PLL3 Main Clock	input	480	
PLL3 PFD3 Clock	input	308	
PLL3 PFD4 Clock	input	320	
PLL4 Main Clock	input	1300	
PLL5 Main Clock	input	100	
PLL5 Main Clock	input	1064	
QSPI Serial Clock	output	104	
QSPI SerialX2 Clock	output	160	
QSPI SerialX4 Clock	output	320	
SWO Clock	output	44	
Trace Clock	output	170	
VADC Core Clock	output	133	PLL6 : 1064/8
VADC Div Clock	output	66	

NOTE

Maximum baud rate supported at SPI output (serial) is 83 MHz.

Chapter 10
Clock Controller Module (CCM)

10.1 Introduction

This document describes the Clock Controller Module (CCM). The CCM generates the clocks for all the peripherals.

10.1.1 Overview

The Clock Controller Module controls the following functions:

- Uses the available clock sources to generate clock roots to various parts of the device
- Uses programmable bits to control frequencies of the clock roots
- Controls the low power mechanism
- Provides control signals to Low Power Clock Gating module (LPCG) for gating clocks
- Provides handshake with System Reset Controller (SRC) for reset performance
- Provides handshake with Global Power Controller (GPC) for low power mode operations

10.1.2 Features

The CCM includes the following features:

- Four sources of clocks: two internal RC oscillators and two crystal oscillators.
- Seven PLLs present in the processor.

PLL	PLL Defintion
PLL1	PLLSYS 528
PLL2	PLL 528

Table continues on the next page...

PLL	PLL Defintion
PLL3	USB0 PLL 480
PLL4	AUDIO PLL
PLL5	ENET PLL
PLL6	VIDEO PLL
PLL7	USB1 PLL

- Separate dividers and clock source selectors for core, bus, and each peripheral's clock.
- External clocks have option to bypass PLL clocks.
- Clock signals can be output on CKO1 and CKO2 pins for observation.
- Registers accessible via IP bus.
- Low Power modes management.
- Programmable clock gating of the peripheral clocks in low power modes.
- Frequency scaling management procedure for ARM core clock by shifting between PLL sources, without loss of clocks.
- Frequency scaling management procedure for peripheral root clock by programmable divider. The division is done on the fly without loss of clocks.

10.1.3 CCM BLOCK DIAGRAM

The CCM contains the following sub-blocks:

Table 10-1. CCM Sub-blocks

CCM_CLK_IGNITION	Manages the ignition process. This module starts its functionality once CCM comes out of reset. It manages the process that begins with starting the osc, PLLs and finishes with creation of stable output root clocks after reset.
CCM_CLK_SRC_DIV	Muxes different clocks and critical internal signals for observability. These output clocks are connected to the pads.
CCM_CLK_ROOT_GEN	Receives the main clocks and generates the output root clocks.
CCM_CLK_MOD_GEN	Generates the accessory clocks.
CCM_REG_IPS	The Register interface for configuring CCM and maintaining status.
CCM_LPM	Manages the low power mode entry and exit sequence.
CCM_CLK_LOGIC	Generates the clock enable signals based on info from CCM_LPM and CCM registers. The clock enables are used in LPCG to turn off and on the module clocks.

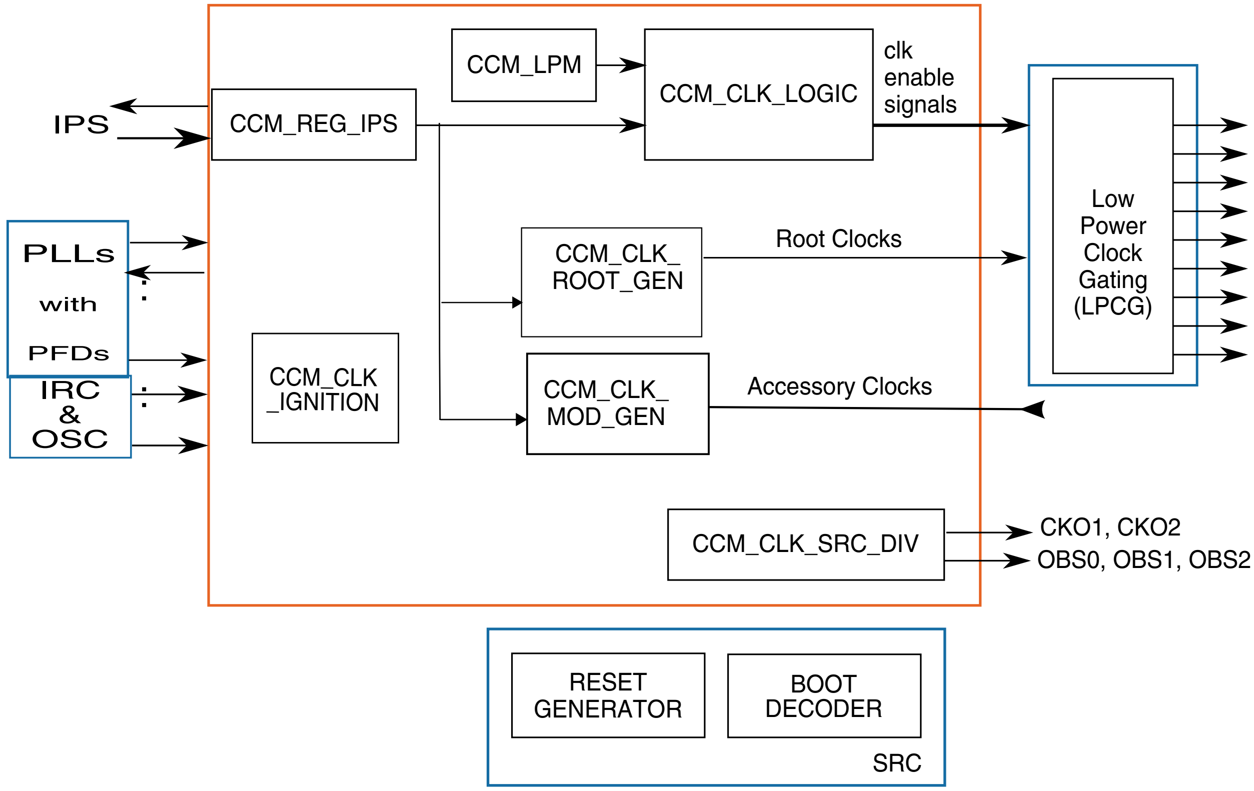


Figure 10-1. Block Diagram

CCM_CCR field descriptions (continued)

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td>16
FIRC_EN</td><td>On-Chip fast RC Oscillator enable bit

0 Disable on-chip RC oscillator
1 Enable on-chip RC oscillator</td></tr>
<tr><td>15–13
Reserved</td><td>This field is reserved.
This read-only field is reserved and always has the value 0.</td></tr>
<tr><td>12
FXOSC_EN</td><td>On-chip fast crystal oscillator (24 MHz FXOSC) enable bit. The system will start with on-chip oscillator enabled to supply source for the PLL’s. Software can change this bit if a transition to the bypass PLL clocks was performed for all the PLLs. In cases that this bit is changed from ‘0’ to ‘1’ then CCM will enable the on-chip oscillator and after counting CCM_CCR[OSCNT] clock cycles it will notify that on-chip oscillator is ready by a interrupt FXOSC_RDY and by status bit FXOSC_RDY. The FXOSC_EN bit should be changed only when on-chip oscillator is not chosen as the clock source.

Table 10-4. CCR[FXOSC_EN] and CLPCR[FXOSC_PWRDWN] behavior

Field	Description
	0001 Divide by 2 ... ... 1111 Divide by 16
19–16 ESDHC0_ DIV[3:0]	Divider to generate ESDHC1 clock 0000 Divide by 1 0001 Divide by 2 ... ... 1111 Divide by 16
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 NFC_CLK_INV	NFC clock phase select 0 Low Phase of NFC clock > 50% 1 High Phase of NFC clock > 50%
13 NFC_FRAC_ DIV_EN	Enables the division in Fraction. If this bit is not set the NFC_FRAC_DIV divider acts as integer divider 0 NFC_FRAC_DIV divider acts as integer divider 1 Fractional 0.5 divider enabled (in addition to FRAC_DIV). Example: When NFC_FRAC_DIV = 1 and NFC_FRAC_DIV_EN =0 the division value is 1. When NFC_FRAC_DIV = 1 and NFC_FRAC_DIV_EN =1 the division value = 1.5.
12 CAN1_EN	CAN1 clock enable 0 Disable CAN1 clock 1 Enable CAN1 clock
11 CAN0_EN	CAN0 clock enable 0 Disable CAN0 clock 1 Enable CAN0 clock
10 Reserved	Reserved This field is reserved. Reserved
9 NFC_EN	NFC clock enable 0 Disable NFC clock 1 Enable NFC clock
8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–4 NFC_FRAC_DIV	Divider to generate NAND Flash Controller clock 0000 Divide by 1 0001 Divide by 2 ... ... 1111 Divide by 16
3–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

10.2.8 CCM Serial Clock Divider Register 3 (CCM_CSCDR3)

The figure below represents the CCM Serial Clock Divider Register 3(CSCDR3). The CSCDR3 register contains bits to control the clock generation sub module dividers. The table below provides its field descriptions.

NOTE

Any change on the dividers have to be done while the module clock is gated.

Address: 4006_B000h base + 1Ch offset = 4006_B01Ch

10.2.10 CCM Testing Observability Register (CCM_CTOR)

The figure below represents the CCM Testing Observability Register (CTOR). CCM includes three muxes to mux between different critical signals for testing observability. The output of the three muxes is generated on the three output signals obs_output_0, obs_output_1, and obs_output_2. Those three output signals can be generated on the IC pads by configuring the IOMUXC. The CTOR register contains bits to control the data generated for observability on the three output signals above. The table below provides its field descriptions.

Address: 4006_B000h base + 28h offset = 4006_B028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

10.2.11 CCM Low Power Control Register (CCM_CLPCR)

The figure below represents the CCM Low Power Control Register (CLPCR). The CLPCR register contains bits to control the low power modes operation.The table below provides its field descriptions.

NOTE

Setting all the bits CCM_CLPCR[M_CORE0_WFI], CCM_CLPCR[M_CORE1_WFI], CCM_CLPCR[M_SCU_IDLE], and

CCM_CLPCR[M_L2CC_IDLE] will result in stop mode or low power stop mode depending upon GPC.

Address: 4006_B000h base + 2Ch offset = 4006_B02Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

CCM_CLPCR field descriptions

Field	Description
31–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 M_L2CC_IDLE	Mask L2CC IDLE for entering low power mode.

Table continues on the next page...

CCM_CLPCR field descriptions (continued)

Field	Description
	0 L2CC IDLE is not masked 1 L2CC IDLE is masked
24 M_SCU_IDLE	Mask SCU IDLE for entering low power mode. 0 SCU IDLE is not masked 1 SCU IDLE is masked
23 M_CORE1_WFI	Mask WFI of core1 for entering low power mode 1 WFI of core1 is masked 0 WFI of core1 is not masked
22 M_CORE0_WFI	Mask WFI of core0 for entering low power mode 0 WFI of core0 is not masked 1 WFI of core0 is masked
21–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19 Reserved	This field is reserved. Umimplemented
18–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 FXOSC_BYPSS	Bypass status of 24 MHz oscillator 0 24 Mhz oscialltor not bypassed 1 24 Mhz oscillator bypassed by external oscillator
11 FXOSC_ PWRDWN	In run mode, software can manually control powering down of on-chip oscillator. If software manually powered down the on-chip oscillator, then standby oscillator functionality for on-chip oscillator will be bypassed. The manual closing of on-chip oscillator should be performed only in case the reference oscilator is not the source of all the clocks generation. 0 On-chip oscillator will not be powered down 1 On-chip oscillator will be powered down
10 FXOSC_ BYPSEN	24 Mhz Oscillator bypass enable signal. 0 24 Mhz oscillator is not bypassed 1 24 Mhz oscillator is bypassed by external oscillator
9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 ANADIG_STOP_ MODE	Masks the ANADIG stop mode indicator. See ANADIG_ANA_MISC0[STOP_MODE_CONFIG]. 0 Stop Mode indication is masked to Anatop 1 Stop Mode indication is sent to Anatop
7 DIS_REF_OSC	In run mode, software can manually control closing of external reference oscillator clock, i.e. generating '1' on ref_en_b signal. If software closed manually the external reference clock, then sbyos functionality will be bypassed. The manual closing of external reference oscilator should be performed only in case the reference oscilator is not the source of any clock generation.

Table continues on the next page...

CCM_CLPCR field descriptions (continued)

Field	Description
	0 External high frequency oscillator will be enabled, i.e. ref_en_b = '0'.(default) 1 External high frequency oscillator will be disabled, i.e. ref_en_b = '1'
6 SBYOS	Standby clock oscillator bit. This bit defines whether the 24 MHz FXOSC will be powered down in stop mode. This bit is discarded if CCM_CLPCR[FXOSC_PWRDWN] is asserted. 0 On-chip oscillator will not be powered down, after next entrance to stop mode. 1 On-chip oscillator will be powered down, after next entrance to stop mode.
5 ARM_CLK_LPM	Define if ARM clocks (Cortex-A5 and Cortex-M4) will be disabled on wait mode. This is useful for debug mode, when the user still wants to simulate entering wait mode and still keep ARM clock functioning. **NOTE:** Software should not enable ARM power gating in wait mode if this bit is cleared. 0 ARM clock enabled on wait mode. 1 ARM clock disabled on wait mode.
4–3 Reserved	This field is reserved. Reserved
2–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

10.2.12 CCM Interrupt Status Register (CCM_CISR)

The figure below represents the CCM Interrupt Status Register (CISR). This is a write one to clear register. Once a interrupt is generated, software should write one to clear it. The table below provides its field descriptions.

Address: 4006_B000h base + 30h offset = 4006_B030h

CCM_CGPR field descriptions

Field	Description
31–5 Reserved	This field is reserved. Reserved for future use.
4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 QSPIn_ACCZ	Used for passing bus clock as source to QSPI. It overrides CCM_CSCMR1[QSPIn_CLK_SEL]. 0 Clock source to QSPIn depends on CCM_CSCMR1[QSPIn_CLK_SEL] 1 QSPIn clock source is platform bus clock
0 FS_ENABLE	MLB 1024xFs enable 0 1024xFs MLB is disabled 1 1024xFs is enabled

10.2.16 CCM Clock Gating Register (CCM_CCGR*n*)

The figure below represents the CCM Clock Gating Register (CCM_CCGR). These registers define the clock gating for power reduction of each module as shown in Table 10-20 (CG(i) bits). Each CG(i) field consists of two bits. There are 12 CGR registers. The number of registers required is according to the number of peripherals in the system.

NOTE

For modules on multiple AIPS slots, only the first address is used for clock gating.

1–0 CG0	Clock gating enable.

1. Register read or write for any register in the DDR controller requires the DDRMC clock to be configured from CCM_CCSR[DDRC_CLK_SEL] in addition to enabling the clock from the clock gating register: CCM_CCGR6[CG110]

10.2.17 CCM Module Enable Override Register (CCM_CMEOR*n*)

The following figure represents the CCM Module Enable Override Register (CMEOR). The CMEOR register contains bits to override the clock enable signal from the module. These bits are applicable for only those modules whose clocks are enabled by clock enable signal.

MO(i) fields are used to override the clock enable signal from each module independently.

The register mapping (clock enabling conditions for each module) for the different MOR's is same as that for different CGR's, as shown in Table 10-20

NOTE

For modules on multiple AIPS slots, only the first address is used for module enabling.

Table 10-59. MO Bitfield Descriptions

MO Value	Description
0	Don’t override module enable signal
1	Override module enable signal

NOTE

For description of individual field, refer to Peripheral Bridge 0 (AIPS-Lite 0) Memory Map and Peripheral Bridge 1 (AIPS-Lite 1) Memory Map

CCM_CCOWR field descriptions

Field	Description
31–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 AUX_CORE_ WKUP	Wakes up the secondary (non-master) core. 0 Secondary core clock is gated 1 Secondary core clock is enabled
15–0 WAKEUP_KEY	This should be written with key 5A5Ah in order to write to the AUX_CORE_WKUP.

10.2.20 CCM Platform Clock Gating Register (CCM_CCPGR*n*)

The following figure represents the CCM Platform Clock Gating Register (CCPGR). The clock gating Registers define the clock gating for power reduction of each clock (PCG(i) bits). There are four CCPGR registers. The number of registers required is according to the number of peripherals in the system.

Table 10-75. CCPGR mapping table

Registers	AIPS0/1 Slot #	Module Controlled
CCM_CCPGR0[PPCG0]	AIPS0-Slot0	
CCM_CCPGR0[PPCG1]	AIPS0-Slot1	MSCM (CPU Configuration, INTR, OCRAM)

1–0 PPCG0	Platform Peripheral gating definition bits

10.3 Sync Signals

Sync signals are generated for edge alignment.

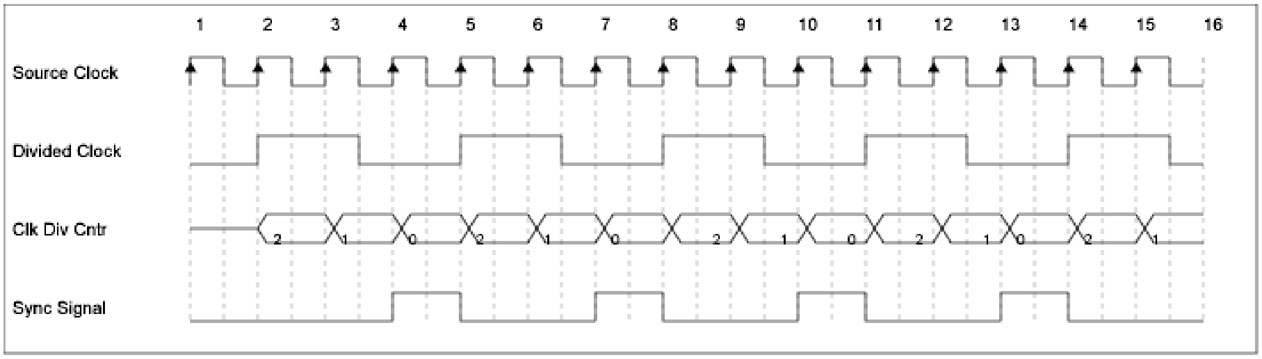

Figure 10-44. Sync Signals

10.4 Accessory clocks

For all the Accessory clock sources muxing it is assumed that clocks will not be switched while running.

10.5 CKIL Synchronizing to ipg_clk

CKIL is synchronized to ipg_clk when system is in functional mode. When system is in stop mode, i.e. when there is no ipg_clk, the CKIL synchronizer will be bypassed, and raw ckil will be supplied to the system.

10.6 Low Power Clock Gating module (LPCG)

The LPCG module receives the root clocks and splits them to clock branches for each module. The clock branches are gated clocks. The enables for those gates can come from the following sources:

- Clock enable signal from CCM — this signal is generated by configuration of the CCM_CCGR bits in CCM. It is based on the low power mode.
- Clock enable signal from the module — this signal is generated by the module based on internal logic of the module. Not every enable signal from the module is used. For clock enable signals from the module, that are used, CCM will generate override signal based on programable bit in CCM_CMEOR.
- Clock enable signal from the System Reset Controller (SRC) — this signal will enable the clock during the reset procedure. See System Reset Controller(SRC) for details on the clock enable signal during reset procedure.
- Hard coded enable from fuse box.

The above possible enable signals are ANDed to generate the enable signal for the gating cell.

The enable signal for the gating cell is synchronized with the clock it needs to gate. This is done in order to prevent glitches on the gated clock.

Notifications are generated for the CCM, to indicate when to close and to open the clock roots. All notifications that correspond to the same clock root will be ORed to generate one notification signal to CCM for clock root gating.

The following figure describes the implementation for each gating cell:

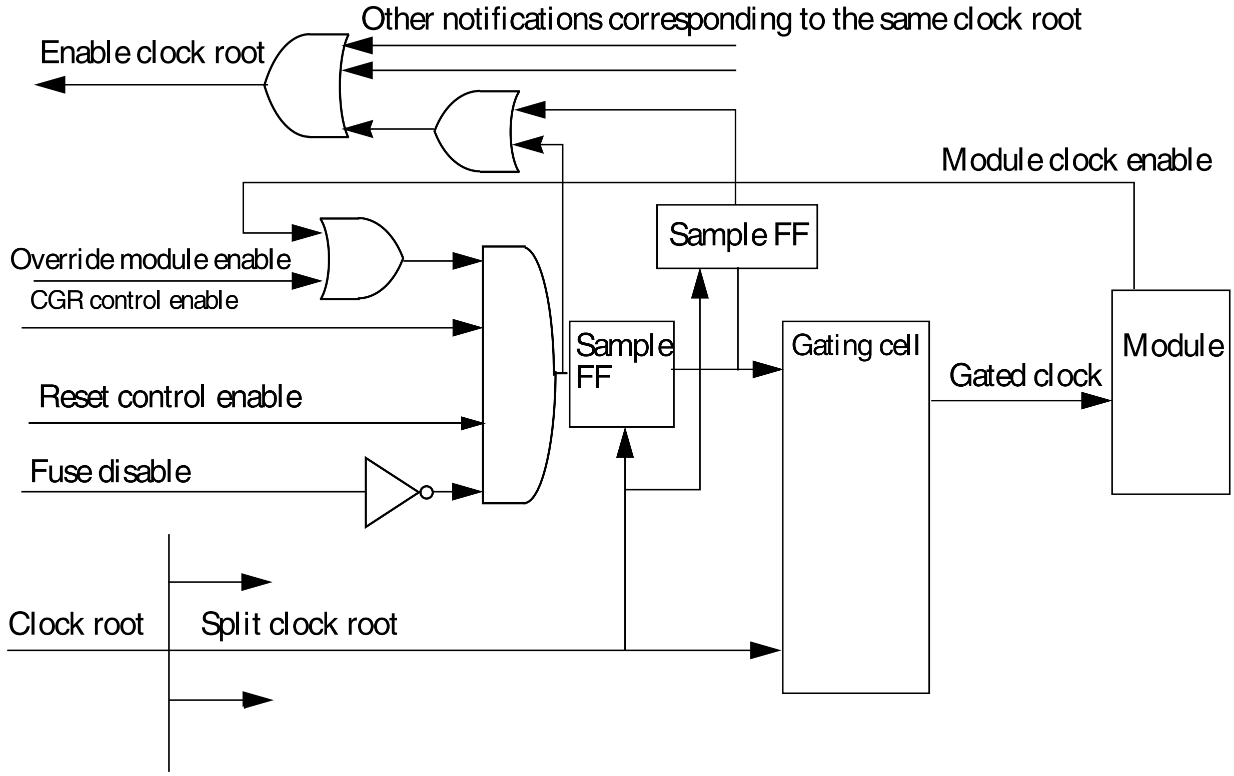

Figure 10-45. Implementation for each gating cell

The following figure describes the clock split inside LPCG module. It describes the case of two modules, one module without enable signal and one with enable signal. (SRC enable signals and sync FFs are omitted from this figure).

10.7 Power modes

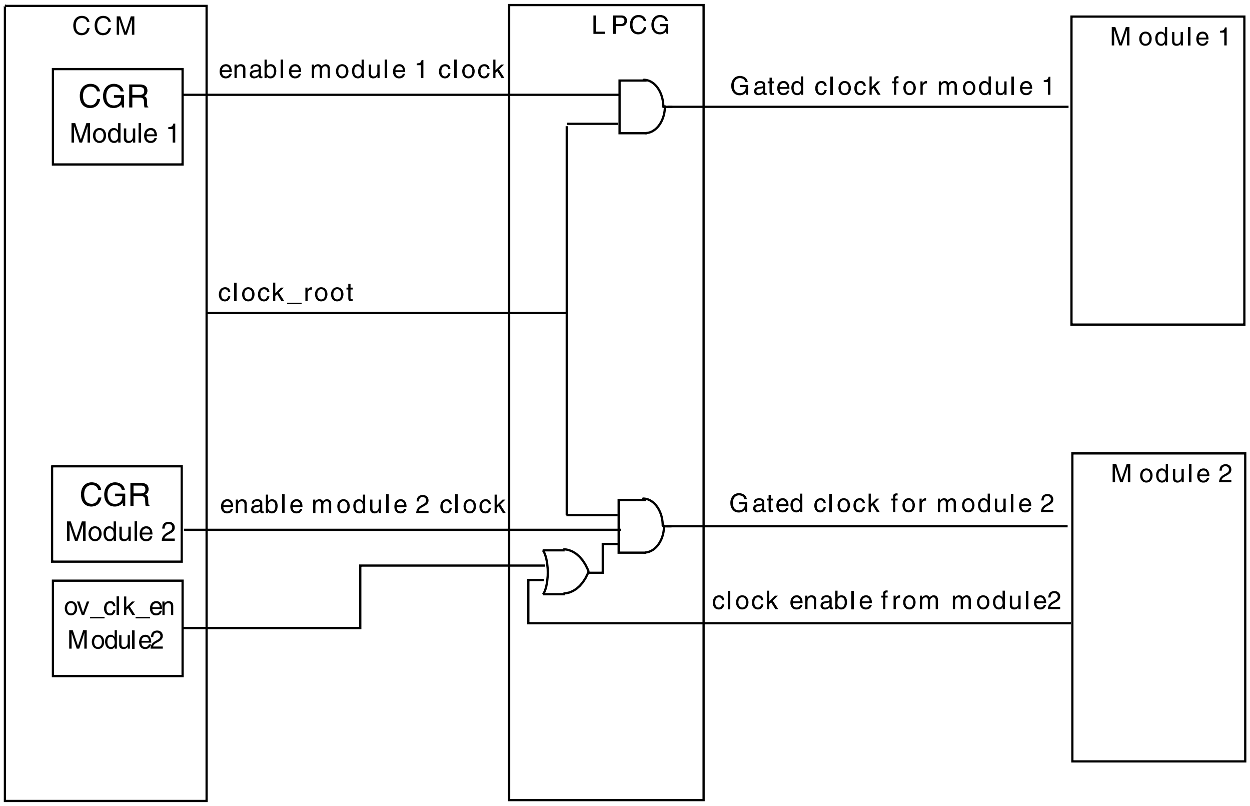

Figure 10-46. Power Modes

CCM supports three low power modes: RUN mode, WAIT mode, and STOP mode.

Chapter 11
Analog components control digital interface (ANADIG)

11.1 Overview

ANADIG is collection of digital interfaces and controllers of analog components, which include control registers described below for controlling analog components and analog interfaces. ANADIG can be accessed through the IPS bus interface.

NOTE

For the ANADIG PLL (including USB PLL), regulator, and miscellaneous registers, the fields are preprogrammed for a configuration and are read-only from a customer perspective.

NOTE

The registers described in this chapter will be referred to from different sections of this Reference Manual.

NOTE

The device has to run on the IRC to detect a BO event on the LDO1p1.

11.2 Memory Map and Registers

11.2.1 Anadig Registers

R	0	BYPASS_CLK_SRC	ENABLE	POWER	0					EN_USB_CLKS	0	0			DIV_SELECT	Reserved
W																
Reset	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

ANADIG_PLL3_CTRL field descriptions

Field	Description
31 LOCK	Lock bit. 0 PLL is not currently locked. 1 PLL is currently locked.
30–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ANADIG_PLL3_CTRL field descriptions (continued)

Field	Description
16 BYPASS	Bypass the PLL. 0 Disable bypass 1 Enable bypass
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 BYPASS_CLK_ SRC	Bypass Clock Source selection. 0 24M XTAL clock is selected as clock source for the PLL. 1 External clock through LVDS pad is selected as clock source for the PLL.
13 ENABLE	Enables the PLL output clock. 0 PLL output clock is gated, so disabled. 1 PLL output clock is enabled.
12 POWER	Powers up the USB0 PLL. 0 Not powered up 1 Powered up
11–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 EN_USB_CLKS	Clock Gating for 8 Phase clock of USB0 PHY. 0 8-phase PLL outputs for USB0 PHY are powered down. 1 8-phase PLL outputs for USB0 PHY are powered up.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 DIV_SELECT	Select PLL multiplication factor (MFI), Fout = Fref * 20 to generates Fout = 480 MHz when Fref = 24 MHz. 0 Fout = Fref*20 (default value) 1 Fout = Fref*22
0 Reserved	This field is reserved.

11.21.2 PLL7 Control register (ANADIG_PLL7_CTRL)

This register defines the control bits for the 480 MHz PLL of USB1.

Address: 4005_0000h base + 20h offset = 4005_0020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Field	Description
16 BYPASS	Bypasses the PLL. 0 Disable bypass 1 Enable bypass
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 BYPASS_CLK_ SRC	Bypass Clock Source selection. 0 24M XTAL clock is selected as clock source for the PLL. 1 External clock through LVDS pad is selected as clock source for the PLL.
13 ENABLE	Enables the clock output. 0 Clock output not enabled 1 Enable clock output
12 POWER	Powers up the USB1 PLL 0 Not powered up 1 Powered up
11–7 Reserved	This field is reserved.
6 EN_USB_CLKS	Clock Gating for 8 Phase clock of USB0 PHY. 0 8-phase PLL outputs for USB1 PHY are powered down. 1 8-phase PLL outputs for USB1 PHY are powered up.
5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 DIV_SELECT	Select PLL multiplication factor (MFI), Fout = Fref * 20 to generates Fout = 480 MHz when Fref = 24 MHz. 0 Fout = Fref * 20 (default value) 1 Fout = Fref * 22
0 Reserved	This field is reserved.

11.21.3 PLL2 Control register (ANADIG_PLL2_CTRL)

This register defines the control bits for the 528 MHz PLL.

Address: 4005_0000h base + 30h offset = 4005_0030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	LOCK	0												PFD_OFFSET_EN	DITHER_ENABLE	BYPASS
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	BYPASS_CLK_SRC	ENABLE	POWERDOWN	Reserved					0					DIV_SELECT	0
W																
Reset	0	0	1	1	0	0	0	0	0	0	0	0	0	0	0	1

ANADIG_PLL2_CTRL field descriptions

Field	Description
31 LOCK	Lock bit. Shows whether the PLL is locked on the required frequency. 0 PLL is not currently locked. 1 PLL is currently locked.

Table continues on the next page...

ANADIG_PLL2_CTRL field descriptions (continued)

Field	Description
30–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 PFD_OFFSET_ EN	Enables an offset in the phase frequency detector. 0 Offset in the phase frequency detector is not enabled 1 Enable an offset in the phase frequency detector
17 DITHER_ ENABLE	Enables dither in the fractional modulator calculation. 0 Dither in the fractional modulator calculation is not enabled 1 Enable dither in the fractional modulator calculation.
16 BYPASS	Bypasses the PLL The frequency that is at the input of the PLL circumvents the PLL and is routed directly to the output of the PLL, i.e., the PLL has no affect on the frequency. If this bit is set, the outplut will be either 24MHz xtal clock or external clock through LVDS pad depending on the BYPASS_CLK_SOURCE bit. 0 Disable bypass 1 Enable bypass
15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
14 BYPASS_CLK_ SRC	Bypass Clock Source selection. 0 24M XTAL clock is selected as clock source for the PLL 1 External clock through LVDS pad is selected as clock source for the PLL.
13 ENABLE	Enables the PLL output clock. 0 PLL output clock is gated, so disabled. 1 PLL output clock is enabled.
12 POWERDOWN	Powers down the PLL. 0 PLL is not powered down 1 Power down the PLL
11–7 Reserved	This field is reserved.
6–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 DIV_SELECT	Frequency multipler selection (MFI). 0 Fout = Fref * 20 1 Fout = Fref * 22. If PLL frequency is to be 528MHz, Fout = 528 MHz = 24 MHz xtal * 22.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.21.4 PLL2 Spread Spectrum definition register (ANADIG_PLL2_SS)

This register defines the control bits for the 528 MHz PLL.

Address: 4005_0000h base + 40h offset = 4005_0040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R/W	STOP															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	ENABLE	STEP														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ANADIG_PLL2_SS field descriptions

Field	Description
31–16 STOP	STOP and STEP together control the modulation depth (maximum frequency change) and Modulation Depth in the SSCG mode (as per given formula). Modulation Depth = (STOP / MFD) * Fref), where MFD is the MFD field value in PLL2 Denominator definition register (ANADIG_PLL2_DENOM) register. Recommended: Modulation Depth = 2%, Modulation Frequency = 32K Modulation Frequency = (STEP / (2 * STOP)) * Fref, where Fref = 24MHz..
15 ENABLE	This bit enables the spread spectrum modulation. 0 Spectrum modulation is not enabled 1 Enable spectrum modulation
14–0 STEP	STOP and STEP together control the modulation depth (maximum frequency change) and Modulation Depth in the SSCG mode (as per given formula). Modulation Depth = (STOP / MFD) * Fref), where MFD is the MFD field value in PLL2 Denominator definition register (ANADIG_PLL2_DENOM) register. Recommended: Modulation Depth = 2%, Modulation Frequency = 32K Modulation Frequency = (STEP / (2 * STOP)) * Fref, where Fref = 24MHz..

11.21.5 PLL2 Numerator definition register (ANADIG_PLL2_NUM)

This register defines the control bits for the 528 MHz PLL.

Address: 4005_0000h base + 50h offset = 4005_0050h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0		MFN																													
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ANADIG_PLL2_NUM field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–0 MFN	30-bit numerator of the fractional loop divider (unsigned integer). **NOTE:** These bits are preset to required values that are within the range of the PLL. **NOTE:** Zero is an invalid value. **NOTE:** The value of the numerator must always be configured to be less than the value of the denominator.

11.21.6 PLL2 Denominator definition register (ANADIG_PLL2_DENOM)

This register defines the control bits for the 528 MHz PLL.

Address: 4005_0000h base + 60h offset = 4005_0060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ANADIG_PLL2_DENOM field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–0 MFD	30-bit denominator of the fractional loop divider (unsigned integer). **NOTE:** These bits are preset to required values that are within the range of the PLL. **NOTE:** Zero is an invalid value. **NOTE:** The value of the numerator must always be configured to be less than the value of the denominator.

11.21.7 PLL4 Control register (ANADIG_PLL4_CTRL)

This register defines the control bits for the audio PLL.

Address: 4005_0000h base + 70h offset = 4005_0070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	BYPASS_CLK_SRC	ENABLE	POWERDOWN	0					DIV_SELECT						
W																
Reset	0	0	0	1	0	0	0	0	0	0	1	1	0	0	0	1

ANADIG_PLL4_CTRL field descriptions

Field	Description
31 LOCK	Lock bit. 0 PLL is not currently locked. 1 PLL is currently locked.
30–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ANADIG_PLL4_CTRL field descriptions (continued)

Field	Description
20–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 PFD_OFFSET_ EN	Enables an offset in the phase frequency detector. 0 PFD offset is not enabled 1 Enable PFD offset
17 DITHER_ ENABLE	Enables dither in the fractional modulator calculation. 0 Dither is not enabled 1 Enable ditther
16 BYPASS	Bypasses the PLL. 0 No Bypass, PLL will drive its own Clock 1 Enable bypass
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 BYPASS_CLK_ SRC	Bypass Colock Source selection. 0 24M XTAL clock is selected as clock source for the PLL. 1 External clock through LVDS pad is selected as clock source for the PLL.
13 ENABLE	Enables the clock output. 0 PLL output clock is disabled. 1 PLL output clock is enabled.
12 POWERDOWN	Powers down the PLL. 0 No Power Down 1 PLL Power Down
11–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–0 DIV_SELECT	Frequency multipler factor selection. Freq = InputFreq (24MHz for Xtal) * DIV_SELECT **NOTE:** This PLL can function from 600MHz to 1300MHz.. **NOTE:** Zero is an invalid value.

11.21.8 PLL4 Numerator register (ANADIG_PLL4_NUM)

This register defines the control bits for the audio PLL.

Address: 4005_0000h base + 80h offset = 4005_0080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ANADIG_PLL5_CTRL field descriptions

Field	Description
31 LOCK	Lock bit.

Table continues on the next page...

ANADIG_PLL5_CTRL field descriptions (continued)

Field	Description
	0 PLL is not currently locked. 1 PLL is currently locked.
30–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 PFD_OFFSET_EN	Enables an offset in the phase frequency detector. 0 PFD offset is not enabled 1 Enable PFD offset
17 DITHER_ENABLE	Enables dither in the fractional modulator calculation. 0 Dither is not enabled 1 Enable dither
16 BYPASS	Bypasses the PLL.. 0 Bypass is not enabled 1 Enable bypass
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 BYPASS_CLK_SRC	Bypass Clock Source selection. 0 24M XTAL clock is selected as clock source for the PLL. 1 External clock through LVDS pad is selected as clock source for the PLL.
13 ENABLE	Enables the clock output. 0 Clock output is not enabled 1 Enable clock output
12 POWERDOWN	Powers down the PLL. 0 Power down is not enabled 1 Enable power down
11–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–0 DIV_SELECT	Controls the frequency of the Ethernet reference clock. 01 50 MHz

11.21.14 ANADIG PLL3 PFD definition register (ANADIG_PLL3_PFD)

This register defines the control bits for the PFD clocks derived from PLL3 for USB0.

NOTE

It is recommended that PFD setting are kept between 18 and 35 for all PFDs.

NOTE

PLL7 for USB1 does not have PFDs.

Address: 4005_0000h base + F0h offset = 4005_00F0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ANADIG_PLL3_PFD field descriptions

Field	Description
31 PFD4_CLKGATE	This bit controls the generation of PFD4.

Table continues on the next page...

ANADIG_PLL3_PFD field descriptions (continued)

Field	Description
	0 ref_pfd4 fractional divider clock is enabled. 1 ref_pfd4 fractional divider clock is disabled for power savings.
30 PFD4_STABLE	This read-only field is for diagnostic purpose only because the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bits inverts, the phase divider clock ouput is stable. Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
29–24 PFD4_FRAC	This field controls the fractional divide value. The resulting frequency is 480*18/pfd4_frac where the value of pfd4_frac ranges between 12 and 35.
23 PFD3_CLKGATE	This bit controls the generation of PFD3. 0 ref_pfd3 fractional divider clock is enabled. 1 ref_pfd3 fractional divider clock is disabled for power savings.
22 PFD3_STABLE	This read-only bitfield is for diagnostic purposes only because the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bits inverts, the phase divider clock ouput is stable. Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
21–16 PFD3_FRAC	This field controls the fractional divide value. The resulting frequency shall be 480*18/pfd3_frac where the value of pfd3_frac ranges from 12 to 35.
15 PFD2_CLKGATE	This bit controls the generation of PFD2. 0 ref_pfd2 fractional divider clock is enabled. 1 ref_pfd2 fractional divider clock is disabled for power savings.
14 PFD2_STABLE	This read-only bitfield is for diagnostic purposes only because the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bits inverts, the phase divider clock ouput is stable. Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
13–8 PFD2_FRAC	This field controls the fractional divide value. The resulting frequency is 480*18/pfd2_frac where the value of pfd2_frac ranges from 12 to 35.
7 PFD1_CLKGATE	This bit controls the generation of PFD1. 0 ref_pfd1 fractional divider clock is enabled. 1 ref_pfd1 fractional divider clock is disabled for power saving.
6 PFD1_STABLE	This read-only bitfield is for diagnostic purposes only since the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bits inverts, the phase divider clock ouput is stable. Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
5–0 PFD1_FRAC	This field controls the fractional divide value. The resulting frequency shall be 480 * 18 / pfd1_frac, where the value of pfd1_frac ranges from 12 to 35. **NOTE:** It is recommended that PFD setting is kept between 18 and 35 for all PFDs.

11.21.15 ANADIG PLL2 PFD definition register (ANADIG_PLL2_PFD)

This register defines the control bits for the core PLL.

NOTE

It is recommended that PFD setting is kept between 18 and 35 for all PFDs.

Address: 4005_0000h base + 100h offset = 4005_0100h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ANADIG_PLL2_PFD field descriptions

Field	Description
31 PFD4_CLKGATE	This bit controls the generation of PFD4.

Table continues on the next page...

ANADIG_PLL2_PFD field descriptions (continued)

Field	Description
	0 ref_pfd4 fractional divider clock is enabled. 1 ref_pfd4 fractional divider clock is disabled for power savings.
30 PFD4_STABLE	This read-only field is for diagnostic purpose only because the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bits inverts, the phase divider clock ouput is stable. Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
29–24 PFD4_FRAC	This field controls the fractional divide value. The resulting frequency is 528*18/pfd4_frac where the value of pfd4_frac ranges between 12 and 35.
23 PFD3_CLKGATE	This bit controls the generation of PFD3. 0 ref_pfd3 fractional divider clock is enabled. 1 ref_pfd3 fractional divider clock is disabled for power savings.
22 PFD3_STABLE	This read-only bitfield is for diagnostic purposes only because the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bits inverts, the phase divider clock ouput is stable. Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
21–16 PFD3_FRAC	This field controls the fractional divide value. The resulting frequency shall be 528*18/pfd3_frac where the value of pfd3_frac ranges from 12 to 35.
15 PFD2_CLKGATE	This bit controls the generation of PFD2. 0 ref_pfd2 fractional divider clock is enabled. 1 ref_pfd2 fractional divider clock is disabled for power savings.
14 PFD2_STABLE	This read-only bitfield is for diagnostic purposes only because the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bits inverts, the phase divider clock ouput is stable. Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
13–8 PFD2_FRAC	This field controls the fractional divide value. The resulting frequency is 528*18/pfd2_frac where the value of pfd2_frac ranges from 12 to 35.
7 PFD1_CLKGATE	This bit controls the generation of PFD1. 0 ref_pfd1 fractional divider clock is enabled. 1 ref_pfd1 fractional divider clock is disabled for power saving.
6 PFD1_STABLE	This read-only bitfield is for diagnostic purposes only since the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bits inverts, the phase divider clock ouput is stable. Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
5–0 PFD1_FRAC	This field controls the fractional divide value. The resulting frequency shall be 528*18/pfd1_frac where the value of pfd1_frac ranges from 12 to 35. **NOTE:** It is recommended that PFD setting is kept between 18 and 35 for all PFDs.

11.21.16 ANADIG Regulator 1P1 definition register (ANADIG_REG_1P1)

This register defines the control and status bits for the 1.1 V regulator. This regulator is designed to power the digital portions of the analog cells.

Address: 4005_0000h base + 110h offset = 4005_0110h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0														OK_VDD1P1	BO_VDD1P1
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0												ENABLE_PULLDOWN	ENABLE_ILIMIT	ENABLE_BO	ENABLE_LINREG
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	

ANADIG_REG_1P1 field descriptions

Field	Description
31–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

ANADIG_REG_1P1 field descriptions (continued)

Field	Description
17 OK_VDD1P1	This status bit signals that the regulator output is ok. 0 Regulator output is not ok. 1 Regulator output is ok.
16 BO_VDD1P1	This is the status bit that shows if the regulator Brown-out is asserted of not. Brown out is the point when regulator is unable to hold its output above the configured voltage. 0 Brown-out is not detected on the regulator output. 1 Brown-out is detected on the regulator output.
15–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 ENABLE_ PULLDOWN	Control bit to enable the pull-down circuitry in the regulator. 0 Pull-down circuitry in the regulator is not enabled 1 enable the pull-down circuitry in the regulator.
2 ENABLE_ILIMIT	Control bit to enable the current-limit circuitry in the regulator input power. Once, this bit is asserted, regulator will not sync more current then its limit. 0 Current-limit circuitry in the regulator is not enabled 1 Enable the current-limit circuitry in the regulator.
1 ENABLE_BO	Control bit to enable the brown-out circuitry in the regulator. 0 Brown-out circuitry in the regulator is not enabled 1 Enable the brown-out circuitry in the regulator.
0 ENABLE_ LINREG	Control bit to enable the regulator output. 0 Regulator output is not enabled 1 Enable the regulator output.

11.21.17 ANADIG Regulator 3P0 definition register (ANADIG_REG_3P0)

This register defines the control and status bits for the 3.0 V regulator powered by the host USB V_{BUS} pin.

Address: 4005_0000h base + 120h offset = 4005_0120h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0														OK_VDD3P0	BO_VDD3P0

R	0								REG_3P0_VBUS_SEL	0				ENABLE_ILIMIT	ENABLE_BO	ENABLE_LINREG
W									REG_3P0_VBUS_SEL					ENABLE_ILIMIT	ENABLE_BO	ENABLE_LINREG
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

ANADIG_REG_3P0 field descriptions

Field	Description
31–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 OK_VDD3P0	This status bit signals that the regulator output is ok. 0 Regulator output is not ok 1 Regulator output is ok
16 BO_VDD3P0	This is the status bit that shows if the regulator Brown-out is asserted of not. Brown out is the point when regulator is unable to hold its output above the configured voltage. 0 Brown-out is not detected on the regulator output. 1 Brown-out is detected on the regulator output.
15–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7 REG_3P0_ VBUS_SEL	If both V_{BUS} host and V_{BUS} otg are detected present, then this bit determines which source is utilized for generating reg_3p0. 0 Utilize host power. 1 Utilize OTG power.
6–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2 ENABLE_ILIMIT	Control bit to enable the current-limit circuitry in the regulator input power. Once, this bit is asserted, regulator will not sync more current then its limit. 0 Current-limit circuitry in the regulator is not enabled 1 Enable the current-limit circuitry in the regulator
1 ENABLE_BO	Control bit to enable the brown-out circuitry in the regulator. 0 Brown-out circuitry in the regulator is not enabled 1 Enable the brown-out circuitry in the regulator
0 ENABLE_ LINREG	Control bit to enable the regulator output. 0 Regulator output is not enabled 1 Enable the regulator output.

11.21.18 ANADIG Regulator 2P5 definition register (ANADIG_REG_2P5)

This register defines the control and status bits for the 2.5 V regulator.

Address: 4005_0000h base + 130h offset = 4005_0130h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0													ENABLE_WEAK_LINREG	OK_VDD2P5	BO_VDD2P5
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0												ENABLE_PULLDOWN	ENABLE_ILIMIT	ENABLE_BO	ENABLE_LINREG
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

ANADIG_REG_2P5 field descriptions

Field	Description
31–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 ENABLE_ WEAK_LINREG	Enables the weak 2p5 regulator. This regulator is used when the main 2p5 regulator is disabled to keep the 2.5 V output roughly at 2.5 V. It depends directly on the value of VDDIO. The same enable is also used to enable the weak 1p1 regulator. This regulator is used when the main 1p1 regulator is disabled to keep the 1.1V output roughly at 1.1V. **NOTE:** Setting this bit is mandatory for wake-up from USB in stop mode when main regulators (1p1 and 2p5) are turned off. Weak Linreg (1p1 and 2p5) are enabled in stop mode to support wake-up from USB. 0 Weak 2p5 regulator is not enabled 1 Enable the weak 2p5 regulator
17 OK_VDD2P5	Status bit that signals when the regulator output is ok. 0 Regulator output is not ok. 1 Regulator output is ok.
16 BO_VDD2P5	This is the status bit that shows if the regulator Brown-out is asserted of not. Brown out is the point when regulator is unable to hold its output above the configured voltage. Brown-out is not detected on the regulator output. Brown-out is detected on the regulator output.
15–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 ENABLE_ PULLDOWN	Control bit to enable the pull-down circuitry in the regulator. 0 Pull-down circuitry in the regulator is not enabled 1 Enable the pull-down circuitry in the regulator
2 ENABLE_ILIMIT	Control bit to enable the current-limit circuitry in the regulator. 0 Current-limit circuitry in the regulator is not enabled 1 Enable the current-limit circuitry in the regulator
1 ENABLE_BO	Control bit to enable the brown-out circuitry in the regulator. 0 Brown-out circuitry in the regulator is not enabled 1 Enable the brown-out circuitry in the regulator
0 ENABLE_ LINREG	Control bit to enable the regulator output. 1 Regulator output is not enabled 0 Enable the regulator output.

11.21.19 ANADIG Analog Miscellaneous definition register (ANADIG_ANA_MISC0)

This register defines the control and status bits for miscellaneous analog blocks.

Address: 4005_0000h base + 150h offset = 4005_0150h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0			0											OSC_XTALOK_EN	OSC_XTALOK
W																
Reset	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0		CLK_24M_IRC_XTAL_SEL	STOP_MODE_CONFIG	0				REFTOP_VBGUP	0			REFTOP_SELBIASOFF	REFTOP_LOWPOWER	REFTOP_PWDVBGUP	REFTOP_PWD
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ANADIG_ANA_MISC0 field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 OSC_XTALOK_ EN	Oscillator Crystal Lock Enable 0 Oscillator crystal lock is not enabled 1 Enable the oscillator crystal lock
16 OSC_XTALOK	Status bit which signals that the output of the 24 MHz crystal oscillator is stable. Generated from a timer and active detection of the actual frequency. 0 Output of the 24 MHz crystal oscillator is not stable 1 Output of the 24 MHz crystal oscillator is stable
15–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13 CLK_24M_IRC_ XTAL_SEL	Select internal 24M IRC clock or External 24M xtal clock as a source of 24MHz. 0 External 24Mhz Xtal Clock 1 24MHz Internal IRC. It is recommended to not use internal IRC for enabling PLL's.
12 STOP_MODE_ CONFIG	Configure the analog behavior in stop mode. 0 All analog except rtc powered down on stop mode assertion. 1 On the device Anatop, just the Reftop (reference bias circuit) can be kept alive in Stop mode. **NOTE:** To support wake-up from USB (Device Mode) , this bit must be set to '1' if 'analog_stop_mode' is used in stop mode (i.e if 'analog_stop_mode bit is set '1' in CCM Low Power Control Register).
11–8 Reserved	This read-only field is reserved and always has the value 0.
7 REFTOP_ VBGUP	This field signals that the analog bandgap voltage is up and stable. 0 Analog bandgap voltage is not up and stable 1 Analog bandgap voltage is up and stable
6–4 Reserved	This read-only field is reserved and always has the value 0.
3 REFTOP_ SELBIASOFF	Control bit to disable the self-bias circuit in the analog bandgap. The self-bias circuit is used by the bandgap during startup. This field should be set after the bandgap has stabilized and is necessary for best noise performance of analog blocks using the outputs of the bandgap. 0 Self-bias circuit in the analog bandgap is not diabled 1 Disable the self-bias circuit in the analog bandgap
2 REFTOP_ LOWPOWER	Control bit to enable the low-power mode in the analog bandgap. 0 Low-power mode in the analog bandgap is not enabled 1 Enable the low-power mode in the analog bandgap
1 REFTOP_ PWDVBGUP	Control bit to power-down the VBG-up detection circuitry in the analog bandgap. 0 VBG-up detection circuitry in the analog bandgap is not powered down 1 Power-down the VBG-up detection circuitry in the analog bandgap

Table continues on the next page...

ANADIG_ANA_MISC0 field descriptions (continued)

Field	Description
0 REFTOP_PWD	Control bit to power-down the analog bandgap reference circuitry. 0 Analog bandgap reference circuitry is not powered down 1 Powerdown the analog bandgap reference circuitry

11.21.20 ANADIG Analog Miscellaneous definition register (ANADIG_ANA_MISC1)

This register defines the control and status bits for miscellaneous analog blocks. The lvds1 and lvds2 controls below control the behavior of the anaclk1/1b and anaclk2/2b lvds IOs.

Address: 4005_0000h base + 160h offset = 4005_0160h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	IRQ_ANA_BO	IRQ_TEMPSENSE	0												
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0			LVDSCLK1_IBEN	0	LVDSCLK1_OBEN	0					0				
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ANADIG_ANA_MISC1 field descriptions

Field	Description
31 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
30 IRQ_ANA_BO	This status bit is set to one when when any of the analog regulator brownout interrupts assert. Check the regulator status bits to discover which regulator interrupt asserted. To clear this bit write a 1 in Clear SCT mode. 0 None of the analog regulator brownout interrupts is asserted 1 Set to one when when any of the analog regulator brownout interrupts is asserted
29 IRQ_ TEMPSENSE	This status bit is set to one when when the temperature sensor interrupt asserts. To clear this bit write a 1 in Clear SCT mode.

Table continues on the next page...

ANADIG_ANA_MISC1 field descriptions (continued)

Field	Description
	0 Temperature sensor interrupt is not asserted 1 Set to one when when the temperature sensor interrupt is asserted
28–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 LVDSCLK1_ IBEN	This enables the lvds input buffer for AnaClock. Do not enable input and output buffers simutaneously. 0 LVDs input buffer not enabled for AnaClock 1 Enable the LVDs input buffer for AnaClock
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 LVDSCLK1_ OBEN	This bit enables the lvds output buffer for selected internal clock. **NOTE:** Do not enable input and output buffers simultaneously. 0 LVDs output buffer is not enabled for driving internal clock 1 Enable the LVDs output buffer for driving internal clock
9–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.21.21 ANADIG Digital Program register (ANADIG_ANADIG_DIGPROG)

Address: 4005_0000h base + 260h offset = 4005_0260h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

R	0	BYPASS_CLK_SRC	ENABLE	POWERDOWN	Reserved					0					DIV_SELECT	0
W																
Reset	0	0	1	1	0	0	0	0	0	0	0	0	0	0	0	1

ANADIG_PLL1_CTRL field descriptions

Field	Description
31 LOCK	Lock bit. Shows whether the PLL is locked on the required frequency. 0 PLL is not currently locked. 1 PLL is currently locked.

Table continues on the next page...

ANADIG_PLL1_CTRL field descriptions (continued)

Field	Description
30–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18 PFD_OFFSET_ EN	Enables an offset in the phase frequency detector. 0 Offset in the phase frequency detector is not enabled 1 Enable an offset in the phase frequency detector
17 DITHER_ ENABLE	Enables dither in the fractional modulator calculation. 0 Dither in the fractional modulator calculation is not enabled 1 Enable dither in the fractional modulator calculation.
16 BYPASS	Bypasses the PLL The frequency that is at the input of the PLL circumvents the PLL and is routed directly to the output of the PLL, i.e., the PLL has no affect on the frequency. If this bit is set, the outplut will be either 24MHz xtal clock or external clock through LVDS pad depending on the BYPASS_CLK_SOURCE bit. 0 Disable bypass 1 Enable bypass
15 Reserved	Reserved. This field is reserved. This read-only field is reserved and always has the value 0.
14 BYPASS_CLK_ SRC	Bypass Clock Source. 0 24M XTAL clock is selected as clock source for the PLL 1 External clock through LVDS pad is selected as clock source for the PLL.
13 ENABLE	Enables the PLL output clock. 0 PLL output clock is gated, so disabled. 1 PLL output clock is enabled.
12 POWERDOWN	Powers down the PLL. 0 PLL is not powered down 1 Power down the PLL
11–7 Reserved	This field is reserved.
6–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 DIV_SELECT	Frequency multipler selection. 00 Fout = Fref * 20 01 Fout = Fref * 22
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

11.21.23 PLL1 Spread Spectrum register (ANADIG_PLL1_SS)

This register defines the control bits for the 528 MHz PLL.

Address: 4005_0000h base + 280h offset = 4005_0280h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ANADIG_PLL1_SS field descriptions

Field	Description
31–16 STOP	STOP and STEP together control the modulation depth (maximum frequency change) and Modulation Depth in the SSCG mode (as per given formula). Modulation Depth = (STOP / B) * Fref), where B is the B field value in PLL2 Denominator definition register (ANADIG_PLL2_DENOM) register. Recommended: Modulation Depth = 2%, Modulation Frequency = 32K Modulation Frequency = (STEP / (2 * STOP)) * Fref, where Fref = 24MHz..
15 ENABLE	This bit enables the spread spectrum modulation. 0 Spread spectrum modulation is not enabled 1 Enable spread spectrum modulation
14–0 STEP	STOP and STEP together control the modulation depth (maximum frequency change) and Modulation Depth in the SSCG mode (as per given formula). Modulation Depth = (STOP / B) * Fref), where B is the B field value in PLL2 Denominator definition register (ANADIG_PLL2_DENOM) register. Recommended: Modulation Depth = 2%, Modulation Frequency = 32K Modulation Frequency = (STEP / (2 * STOP)) * Fref, where Fref = 24MHz..

11.21.24 PLL1 Numerator register (ANADIG_PLL1_NUM)

This register defines the control bits for the 528 MHz PLL.

Address: 4005_0000h base + 290h offset = 4005_0290h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

* Notes:
- x = Undefined at reset.

ANADIG_PLL1_PFD field descriptions

Field	Description
31 PFD4_CLKGATE	This bit enables the fractional divider clock. 0 ref_pfd4 fractional divider clock is enabled. 1 ref_pfd4 fractional divider clock is disabled for power savings.
30 PFD4_STABLE	This read-only bitfield is for diagnostic purpose only because the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bits inverts, the phase divider clock ouput is stable. Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
29–24 PFD4_FRAC	This field controls the fractional divide value. The resulting frequency will be 528*18/pfd4_frac where the value of pfd4_frac ranges from 12 to 35.
23 PFD3_CLKGATE	This bit enables the fractional divider clock. 0 ref_pfd3 fractional divider clock is enabled. 1 ref_pfd3 fractional divider clock is disabled for power savings.
22 PFD3_STABLE	This read-only bitfield is fordiagnostic purposes only because the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bits inverts, the phase divider clock ouput is stable. Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
21–16 PFD3_FRAC	This field controls the fractional divide value. The resulting frequency shall be 528*18/pfd3_frac where the value of pfd3_frac ranges from 12 to 35.
15 PFD2_CLKGATE	This bit controls the generation of PFD2. 0 ref_pfd2 fractional divider clock is enabled. 1 ref_pfd2 fractional divider clock is disabled for power savings.
14 PFD2_STABLE	This read-only bitfield is for diagnostic purposes only because the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bits inverts, the phase divider clock ouput is stable. Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
13–8 PFD2_FRAC	This field controls the fractional divide value. The resulting frequency is 480*18/pfd2_FRAC where the value of pfd2_FRAC ranges from 12 to 35.
7 PFD1_CLKGATE	This bit enables the fractional divider clock. 0 ref_pfd1 fractional divider clock is enabled. 1 ref_pfd1 fractional divider clock is disabled for power saving.
6 D1_STABLE	This read-only bitfield is for diagnostic purposes only because the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bits inverts, the phase divider clock ouput is stable. Note that the value will not invert when the fractional divider is taken out of or placed into the clock-gated state.
5–0 PFD1_FRAC	This field controls the fractional divide value. The resulting frequency shall be 528*18/pfd1_frac where the value of pfd1_frac ranges from 12 to 35.

11.21.27 ANADIG PLL Lock register (ANADIG_PLL_LOCK)

This register give lock status of different PLLs controlled by ANADIG.

Address: 4005_0000h base + 2C0h offset = 4005_02C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0									PLL1	PLL2	PLL4	PLL6	PLL5	PLL3	PLL7

ANADIG_PLL_LOCK field descriptions

Field	Description
31–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6 PLL1	This bit shows if PLL1 (528 SYS) is locked. 0 PLL7 not locked yet. 1 PLL7 locked.
5 PLL2	This bit shows id PLL2 (528) is locked. 0 PLL3 not locked yet. 1 528 PLL3 locked.
4 PLL4	This bit shows if PLL4 (Audio) is locked. 0 PLL5 not locked yet. 1 PLL5 locked.
3 PLL6	This bit shows if PLL6 (Video) is locked. 0 PLL6 not locked yet. 1 PLL6 locked.
2 PLL5	This bit shows if PLL5 (ENET)is locked. 0 PLL4 not locked yet. 1 PLL4 locked.
1 PLL3	This bit shows if PLL3 (USB0) is locked. 0 PLL2 not locked yet. 1 PLL2 locked.
0 PLL7	This bit shows if PLL7 (USB1) is locked. 0 PLL1 not locked yet. 1 PLL1 locked.

Chapter 12
Slow Clock Source Controller Module (SCSC)

12.1 Introduction

The Slow Clock Source Controller (SCSC) module configures the SIRC and SOSC controls. It is alive in standby mode and also in case of power failure. Power Failure implies when VDDIO (3V3) or VDD_SOC (1V2) are not available.

- SIRC- 128kHz controller:

XTAL_OK	Power Fail	SIRC CONTROL
0	0	SIRC_EN
1	0	SIRC_EN
0	1	SIRC_EN_ON_FAIL
1	1	0 - SIRC will be disabled

- RC trims coming from fuse box controller are latched to retain the value in standby.
- SOSC - 32 KHz controller
  - Controls the enable signal.
  - Controls the bypass.

12.2 Memory Map and Registers

SCSC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4005_2000	SIRC Control Register (SCSC_SIRC_CTR)	32	R/W	0000_FF11h	12.2.1/730
4005_2004	SOSC Control (SCSC_SOSC_CTR)	32	R/W	7CFF_0000h	12.2.2/731

12.2.1 SIRC Control Register (SCSC_SIRC_CTR)

Address: 4005_2000h base + 0h offset = 4005_2000h

Chapter 13
Clock Monitor Unit (CMU)

13.1 Introduction

The Clock Monitor Unit (CMU), also referred to as Clock Quality Checker or Clock Fault Detector, serves three purposes:

- Measures the frequency of clock source CLKMT0_RMN with CLKMN0_RMT as the reference clock
- Monitors CLKMN0_RMT frequency with CLKMT0_RMN as reference clock
- Monitors CLKMN1 frequency with CLKMT0_RMN as reference clock and detects if the monitored clock frequency leaves an upper or lower frequency boundary

One of the tasks is to supervise the integrity of the various clock sources on the chip, for example CLKMN0_RMT or CLKMN1. If the monitored clock frequency is less than the reference clock, or it violates an upper or lower frequency boundary, the CMU detects and reports this event.

The CMU can monitor CLKMN0_RMT, which must have a frequency higher than that of CLKMT0_RMN divided by the factor shown in CMU_CSR[RCDIV], and reports this event. The CMU can also monitor CLKMN1 and generate an event if CLKMN1 is greater than a high frequency boundary or less than a low frequency boundary. The upper and lower frequency boundaries are defined by the CMU High Frequency Reference Register (CMU_HFREFR) and CMU Low Frequency Reference Register (CMU_LFREFR).

The second task of the CMU is to provide a frequency meter, which allows measuring the frequency of a clock source against a reference clock. This is useful to allow the calibration of the metered clocks (such as, CLKMT0_RMN), as well as to be able to correct/calculate the time deviation of a counter that is clocked by the metered clocks.

Note

See the "Clocking" chapter for the number of instances of the CMU in this chip.

13.1.1 Main features

- CLKMT0_RMN frequency measurement with CLKMN0_RMT as reference clock.
- CLKMN0_RMT monitoring with respect to CLKMT0_RMN ÷ n clock.
- Upper or lower frequency boundary monitoring of CLKMN1 with respect to CLKMT0_RMN ÷ 4.
- Event generation for various failures detected inside monitoring unit.

13.2 Block diagram

The block diagram of the CMU module(s) is shown in the “Clocking" chapter of this Reference Manual.

13.3 Signals

The table below describes the signals on the boundary of the CMU (in alphabetical order).

Table 13-1. Signal description

Signal	I/O	Description
CLKMN0_RMT	I	Monitored Clock Signal 0/Metered Clock Signal Reference — Receives a clock signal that the CMU compares to a specified low-limit frequency to determine whether the frequency of the clock signal is greater than the specified limit. Also provides a reference clock signal for all metered clock signals.
CLKMN1	I	Monitored Clock Signal 1 — Receives a clock signal that the CMU compares to specified low-limit and high-limit frequencies to determine whether the frequency of the clock signal is between the specified limits.
CLKMT0_RMN	I	Metered Clock Signal 0/Monitored Clock Signal Reference — Receives a clock signal that the CMU measures against a reference clock frequency. Also provides a reference clock signal for all monitored clock signals.

NOTE

See the "Clocking" chapter for device specific clock sources of each CMU.

13.4 Register description and memory map

This section describes in address order all the CMU registers. Each description includes a standard register diagram with an associated figure number. The CMU memory map is listed in the following table.

NOTE

See "Clocking" chapter for register and field availability details.

CMU memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4006_F000	CMU Control Status Register (CMU_CSR)	32	R/W	See section	13.4.1/735
4006_F004	CMU Frequency Display Register (CMU_FDR)	32	R	0000_0000h	13.4.2/737
4006_F008	CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)	32	R/W	0000_0FFFh	13.4.3/737
4006_F00C	CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)	32	R/W	0000_0000h	13.4.4/738
4006_F010	CMU Interrupt Status Register (CMU_ISR)	32	w1c	See section	13.4.5/738
4006_F018	CMU Measurement Duration Register (CMU_MDR)	32	R/W	0000_0000h	13.4.6/740

13.4.1 CMU Control Status Register (CMU_CSR)

Address: 4006_F000h base + 0h offset = 4006_F000h

* Notes:
- RCDIV field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.
- CKSEL1 field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.
- SFM field: Not all CMU blocks will utilize this feature. See the “Clocking” chapter for CMU implementation details.

CMU_CSR field descriptions

Field	Description
0–7 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 SFM	Start frequency measure. The software can only set this bit to start a clock frequency measure. It is reset by hardware when the measure is ready in the CMU_FDR. 0 Frequency measurement is completed or not yet started 1 Frequency measurement is not completed
9–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22–23 CKSEL1	Frequency measure clock selection bit. CKSEL1 selects the clock to be measured by the frequency meter. This only affects CMU instances that utilizes clock metering. Not all CMU blocks will utilize this feature. See the “Clocking” chapter for device specific CMU implementation details. 00 CLKMT0_RMN is selected 01 Reserved 10 Reserved 11 CLKMT0_RMN is selected
24–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–30 RCDIV	CLKMT0_RMN division factor. These bits specify the CLKMT0_RMN division factor. The output clock frequency is $f_{CLKMT0\_RMN} \div 2^{RCDIV}$. This output clock is used as reference clock to compare with CLKMN0_RMT for crystal clock monitor feature. 00 CLKMT0_RMN ÷ 1 (No division) 01 CLKMT0_RMN ÷ 2 10 CLKMT0_RMN ÷ 4 11 CLKMT0_RMN ÷ 8
31 CME	CLKMN1 monitor enable. 0 CLKMN1 monitor is disabled 1 CLKMN1 monitor is enabled

13.4.2 CMU Frequency Display Register (CMU_FDR)

The FDR is used to determine the measured frequency being monitored by the CMU.

Address: 4006_F000h base + 4h offset = 4006_F004h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0												FD																			
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CMU_FDR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 FD	Measured frequency bits. This register displays the measured frequency (f_{sel}) with respect to the reference clock (f_{CLKMN0_RMT}). The measured value is given by the following formula: $f_{sel} = (f_{CLKMN0\_RMT} \times$ CMU_MDR[MD]) ÷ CMU_FDR[FD]

13.4.3 CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)

The HFREFR is configured for the high frequency reference that the CMU will use for comparing against the monitored clock.The figure and table below show the HFREFR register.

Address: 4006_F000h base + 8h offset = 4006_F008h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

CMU_HFREFR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

CMU_HFREFR field descriptions (continued)

Field	Description
20–31 HFREF	High Frequency reference value. These bits determine the high reference value for the CLKMN1 frequency. The reference value is given by: (HFREF ÷ 16) × (f_{CLKMT0_RMN} ÷ 164).

13.4.4 CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)

The LFREFR is configured for the low frequency reference that the CMU will use for comparing against the monitored clock. The figure and table below show the LFREFR register.

Address: 4006_F000h base + Ch offset = 4006_F00Ch

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0																				LFREF											
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CMU_LFREFR field descriptions

Field	Description
0–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–31 LFREF	Low Frequency reference value. These bits determine the low reference value for the CLKMN1 frequency. The reference value is given by: (LFREF ÷ 16) × (f_{CLKMT0_RMN} ÷ 4).

13.4.5 CMU Interrupt Status Register (CMU_ISR)

NOTE

All the flags in CMU_ISR register set asynchronously. This register must be read only after an interrupt is triggered by the CMU. Otherwise, the read access on this register may fetch an incorrect value.

NOTE

Before entering low-power stop modes, all clock frequency measurements in CMU should be disabled. Failing to do so may result in spurious interrupts.

Address: 4006_F000h base + 10h offset = 4006_F010h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W														w1c	w1c	w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0*

* Notes:
- OLRI field: Not all CMU blocks will utilize this feature. See the "Clocking" chapter for specific CMU implementation details.

CMU_ISR field descriptions

Field	Description
0–27 Reserved	This field is reserved.
28 Reserved	This field is reserved.
29 FHHI	CLKMN1 frequency higher than high reference event status. This bit is set by hardware when CLKMN1 frequency becomes higher than HFREF value and CLKMN1 is 'ON'. It can be cleared by software by writing '1'. 0 No FHH event 1 FHH event occurred
30 FLLI	CLKMN1 frequency less than low reference event status. This bit is set by hardware when CLKMN1 frequency becomes lower than LFREF value, and CLKMN1 is 'ON'. Software clears this field by writing a '1'. 0 No FLL event 1 FLL event occurred

Table continues on the next page...

CMU_ISR field descriptions (continued)

Field	Description
31 OLRI	Oscillator frequency less than $f_{CLKMT0\_RMN} \div 2^{RCDIV}$ event status. This bit is set by hardware when the f_{CLKMN0_RMT} is less than $f_{CLKMT0\_RMN} \div 2^{RCDIV}$ frequency and CLKMN0_RMT is 'ON' . It can be cleared by software by writing '1'. 0 No OLR event 1 OLR event occurred

13.4.6 CMU Measurement Duration Register (CMU_MDR)

Address: 4006_F000h base + 18h offset = 4006_F018h

Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0												MD																			
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CMU_MDR field descriptions

Field	Description
0–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–31 MD	Measurement duration bits This field displays the measurement duration in terms of selected clock (CLKMT0_RMN) cycles. This value is loaded in the frequency meter down-counter. The down-counter starts counting when CMU_CSR [SFM] = 1.

13.5 Functional description

13.5.1 Frequency meter

The purpose of the frequency meter is to evaluate the deviation from the nominal metered source (such as CLKMT0_RMN) frequencies. This in turn allows either recalibration of these clocks or other timing corrections. Programming of the CMU_CSR[CKSEL1] field is used to select one of the metered clocks from a multiplexer that drives a simple Frequency Meter (see the CMU Block Diagram in the "Clocking" chapter). The reference clock for the Frequency Meter is the CLKMN0_RMT signal. The measurement starts when CMU_CSR[SFM] = 1. The measurement duration is given by the contents of CMU_MDR[MD] in terms of number of clock cycles of the selected metered clock. The CMU_CSR[SFM] bit is cleared by hardware once the frequency measurement is

complete and the count is loaded in CMU_FDR[FD]. The frequency of the selected clock (f_{sel}) can be derived from the value loaded in the CMU_FDR as shown in the following equation:

$$f_{sel} = f_{CLKMN0\_RMT} \times \frac{CMU\_MDR[MD]}{CMU\_FDR[FD]}$$

13.5.2 CLKMN0_RMT supervisor

If frequency of CLKMN0_RMT is smaller than the frequency of CLKMT0_RMN ÷ $2^{CMU\_CSR[RCDIV]}$ and CLKMN0_RMT is 'ON', then:

- The CMU writes 1 to CMU_ISR[OLRI].
- The CMU asserts the OLR signal.

Note

f_{CLKMN0_RMT} must be greater than $f_{CLKMT0\_RMN} \div 2^{CMU\_CSR[RCDIV]}$ by at least 0.5 MHz in order to guarantee correct f_{CLKMN0_RMT} monitoring.

13.5.3 CLKMN1 supervisor

The frequency of CLKMN1(f_{CLKMN1}) can be monitored by programming CMU_CSR[CME] = 1. CLKMN1 monitoring starts as soon as CMU_CSR[CME] = 1. This monitor can be disabled at any time by programming CMU_CSR[CME] = 0.

If f_{CLKMN1} is greater than the reference value determined by fields CMU_HFREFR[HFREF] and CLKMN1 is 'ON', then:

- The CMU writes 1 to CMU_ISR[FHHI].
- The CMU asserts the FHH signal.

If f_{CLKMN1} is less than a reference value determined by the bits CMU_LFREFR[LFREF] and the CLKMN1 is 'ON', then:

- The CMU writes 1 to CMU_ISR[FLLI].
- The CMU asserts the FLL signal.

Note

f_{CLKMN1} must be greater than f_{CLKMT0_RMN} ÷ 4 by at least 0.5 MHz in order to guarantee correct CLKMN1 monitoring.

Chapter 14
Power management

14.1 Introduction

The power management system on this device has the following capabilities:

- Software-controlled clock gating of peripherals through the CCM module
- Software-controlled enabling/disabling of PLL source through the Anadig registers
- Lowest-power mode features power gating and disabling of all clock sources
- Two power domains (PD0 and PD1) and two voltage domains (1.1V SNVS logic and 1.2V)
- Option to retain 64K, 16K, or no memory for different power-gated (LPStop*n*) modes
- Multiple operating modes to optimize device performance and wake-up times, including
  - Run
  - Low Power Run (LPRun, ULPRun)
  - Stop
  - Low Power Stop (LPStop1, LPStop2, LPStop)

The following figure shows the modules in the power management system and their interaction. The power domains (PD*n*) are described in Power domains.

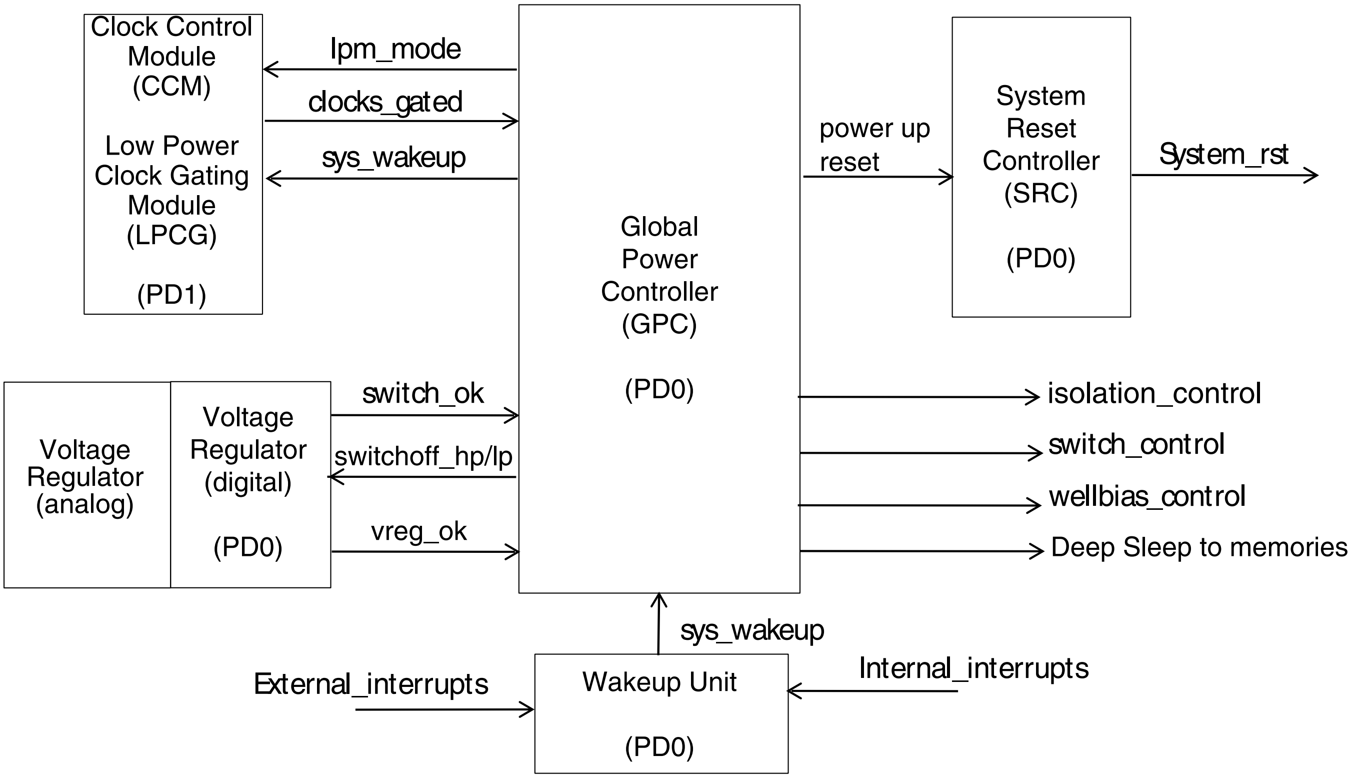

Figure 14-1. Power management modules

14.2 Power domains

The device's modules are partitioned into three logical power domains to allow the user to minimize power consumption by powering off certain functions while retaining only necessary functionality.

Table 14-1. Power domain descriptions

Power Domain	Description	Modules
PD1	Power-gated domain	All modules that are power-gated in LPStop*n* modes
PD0	Always-powered domain. Modules in this domain are operating in LPStop*n* mode.	LPTimer, SRC, VREG_DIG, GPC, WKPU, PMU, FIRC, ADC0, ADC1, LCD, 17 GPIO pads for wakeup
VBAT	The modules in this domain are operational even if there is external supply failure. This domain derives its power from the coin cell.	VBAT contains the SecureRTC, 32KHz XOSC, Tamper, and Monitors. It is powered by a coin cell when the main power supply is switched off.

14.3 Low-power modes

Warning

In order for certain low-power modes to operate as expected, unused TAMPER detection pins must be tied to ground.

The following table shows the device configuration for the various low-power modes. The table also indicates which modules are power-gated, clock-gated, or software configurable. See Power domains for details on what modules are included in the different power domains.

Table 14-2. Power gating and clock gating overview

Domain	Features	Power Gated Modes: SW save and restore[1]			LP Modes: Dynamic Power Saving and Clock Gating Modes[1]		
		LPStop1	LPStop2	LPStop3	Stop	ULPRun	LPRun
PD1	Platform	Off	Off	Off	On	On	On
PD1	Peripherals	Off	Off	Off	Off	Option	Option

1. Option denotes that the application can configure the feature to be On or Off. Recommended configurations are given below.
2. First 64K of SysRAM0
3. First 16K of SysRAM0
4. VBAT contains the RTC, 32kHz XOSC, and Tamper. It is powered by a coin cell when the main power supply is switched off.
5. There are 17 always alive pads which can be used to cause a wakeup event in LPStop*n* modes. See the Pin muxing section for details.

14.3.1 Run mode

In Run mode:

- Device operates at highest rated frequency.
- All device peripherals are operational.

14.3.2 LPRun mode

Low Power Run mode is a software-controlled, dynamic power-saving mode. On reset exit the device is in LPRun mode. All the Arm subsystem clocks are on Fast IRC clock, which is at 24MHz. All the PLLs are in bypassed (Off) state. All the running clocks are scaled down to lower frequencies, from high PLL frequencies to FIRC or FOSC. If some auxiliary clocks, for example the audio subsystem or nand flash clocks, are to be operated at the crystal oscillator clock, then PLLs may be configured to run in bypass mode by configuring the Anadig registers.

Other features of the LPRun mode include:

- The CCM_CCGR register is configured to clock gate the peripherals.
- The PLL and PFD modules are disabled through Anadig.
- FXOSC24 is disabled through the CCM.
- FIRC24 is enabled through the CCM.

14.3.3 ULPRun mode

Ultra-Low Power Run mode is an extension of the LPRun mode allowing the Arm subsystem clock frequencies to be further scaled down to 32KHz or 128KHz.

14.3.4 Wait mode

Wait mode is entered when the GPC_LPMR register is configured for Wait mode and the WFI (Wait For Interrupt) instruction is executed on the core. Wait mode is recommended for applications where the cores can be stalled and other peripherals can operate at a lower frequency.

WFI for an individual core can be executed and GPC_LPMR may not be configured to enter into chip Wait mode. In dual-core configurations, the application can configure WFI to put a single core into halt. Other peripherals can continue operating at the configured frequencies if GPC_LPMR is configured to 00b, i.e., Run mode.

In Wait mode

- CA5 and CM4 cores are halted.
- Normal recovery is from an interrupt.

14.3.5 Stop mode

All clocks to the peripherals are gated by the CCM. Applications should configure that module if any peripherals are to be clocked in Stop mode.

14.3.5.1 Stop mode entry sequence (clock-gating mode)

The following steps must be performed to enter Stop mode.

1. Switch the system clock to 24MHz FIRC by performing the following two steps in order. This is done before disabling any of the primary clock sources (e.g., PLLs, SIRC, SOSC, FOSC) as the low-power state machine needs a running system clock.
   a. Writing 00b to CCM_CCSR[4:5]
   b. Writing 00b to CCM_CCSR[3:0]
2. Disable the PLLs by configuring these Anadig registers
   - Anadig_PLL7_CTRL
   - Anadig_PLL3_CTRL
   - Anadig_PLL2_CTRL
   - Anadig_PLL4_CTRL
   - Anadig_PLL6_CTRL
   - Anadig_PLL5_CTRL
   - Anadig_PLL1_CTRL
3. Write 1 to CCM_CLPCR[ANATOP_STOP_MODE]. This bit determines whether the PMIC_VSTBY_REQ pin (which notifies the external power management IC to switch from functional voltage to standby voltage) will be asserted in Stop mode.
4. Write 10b to GPC_LPMR[CLPCR] to enter Stop mode.
5. Execute the WFI instruction.

14.3.5.2 Optional stop mode entry sequence

This section describes the recommended configuration for advanced power-saving in Stop mode.

When the main 2p5 regulator is disabled, the weak 2p5 regulator can be enabled to keep the 2.5V output at roughly 2.5V, depending on the value of VDDIO. To use this feature, perform the following steps.

1. Write 1 to Anadig_reg_2p5[enable_linreg] to enable regulator output.
2. Write 1 to Anadig_reg_2p5[enable_weak_ linreg] to enable the weak regulator.

In addition, the GPC provides several power-saving options in Stop mode. In Stop mode you can:

- Enable Well Bias by writing 1 to GPC_PGCR[WB_ STOP].
- Turn off HPREG by writing 1 to GPC_PGCR[HP_OFF].
- Enable Deep Sleep for all memories by writing 1 to GPC_PGCR[DS_STOP]. Deep Sleep shuts down power to periphery and maintains memory contents. The outputs of the memory are pulled low.

Lowest-power Stop mode can be achieved by disabling all clock sources through the CCM and SCSC.

14.3.6 LPStop*n* modes

Low Power Stop modes are advanced power saving modes that switch off power to Power Domain 1 (PD1).

Using registers in the GPC, you can configure the device to enter into one of three LPStop modes:

- LPStop1: Lowest power stop mode with no SRAM retained
- LPStop2: 16K RAM is retained
- LPStop3: 64K RAM is retained

It is recommended to keep all the primary clock sources disabled and to wake up from external interrupt sources. Refer to Wakeup Unit (WKPU) for details. If the RTC is to be kept enabled, SOSC can be used as clock source.

14.3.6.1 LPStop*n* mode entry sequence (power-gating mode)

The following steps must be performed to enter LPStop*n* mode.

1. Switch the system clock to 24MHz FIRC by performing the following two steps in order.
    a. Writing 00b to CCM_CCSR[4:5]
    b. Writing 00b to CCM_CCSR[3:0]
2. Disable the PLLs by configuring these Anadig registers
    - Anadig_PLL7_CTRL

- Anadig_PLL3_CTRL
- Anadig_PLL2_CTRL
- Anadig_PLL4_CTRL
- Anadig_PLL6_CTRL
- Anadig_PLL5_CTRL
- Anadig_PLL1_CTRL

3. Write 1 to CCM_CLPCR[ANATOP_STOP_MODE]. This bit determines whether the PMIC_VSTBY_REQ pin (which notifies the external power management IC to switch from functional voltage to standby voltage) will be asserted in Stop mode.
4. Write 10b to GPC_LPMR[CLPCR] to enter Stop mode.
5. Write 1 to GPC_PGCR[PG_PD1] to enter into power gated mode for PD1.
6. Execute the WFI instruction.

14.3.6.2 Optional LPStop*n* mode entry sequence

The GPC provides several power-saving options in LPStop*n* mode. In LPStop*n* mode you can:

- Keep 64KB of System RAM on by writing 0 to GPC_PGCR[PG_16K] and to GPC_PGCR[PG_48K]. Clearing these two bits will cause device to enter LPStop3 mode.
- Disable FIRC during LPStop*n* by writing 0 to CCM_CCR[FIRC_EN].

14.3.7 Interrupt connectivity

This figure shows the interrupt connectivity of the device.

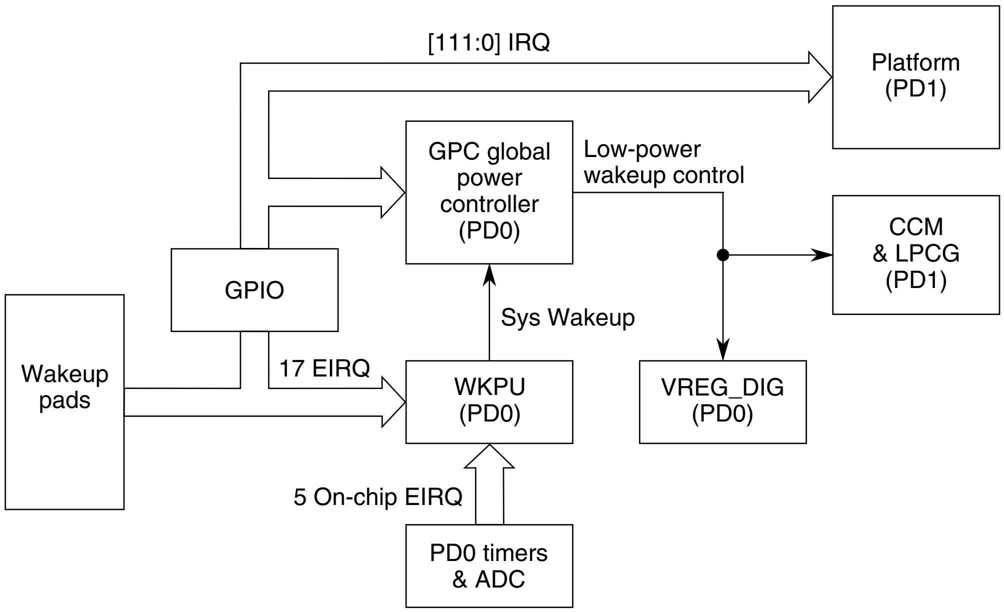

Figure 14-2. Interrupt connectivity

NOTE

- Refer to the GPC_IMR configuration registers for interrupt configurations.
- System can exit from LPStop*n* only through interrupts routed by WKPU.
- All the external IRQs should be level-triggered to cause an exit from Stop mode.
- Refer to Wakeup Unit (WKPU) for on-chip and external wakeup interrupts.

Chapter 15
Global Power Controller (GPC)

15.1 Introduction

The Global Power Controller (GPC) module generates the controls for power gated modes and low power modes. It generally does the isolation of power domain, power gating of power switches and initiates power down to the voltage regulator.

15.2 Features

Key features of the GPC include:

- Power shutdown controller
- Provides the ability to switch off power to a target subsystem.
- Generates power-up and power-down control sequences.
- Provides programmable registers to adjust the timing of the power control signals.

15.3 GPC Memory/Register Map

GPC memory map

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–3 PREV_LPM	Previous Low Power Mode. These bits indicate the previous state of the GPC. 00 RUN mode 01 WAIT mode 10 STOP mode 11 LPSTOPn mode
2–1 CUR_LPM	Current Low Power Mode 00 RUN mode 01 WAIT mode 10 STOP mode 11 LPSTOPn mode
0 PSR	Power status. When in functional (or software-controlled debug) mode, PGC hardware sets PSR as soon as any of the power control output changes its state to one. Write one to clear this bit. Software should clear this bit after power up; otherwise, PSR continues to reflect the power status of the initial power down.

15.3.3 Low Power Mode Register (GPC_LPMR)

The GPC_LPMR register allows the user to configure the low power mode. The following figure shows the register and the table describes the register fields.

NOTE

To enter into LPSTOP mode, CLPCR should be configured to 2'b10 and GPC_PGCR[PG_PD1, PG_64K, PG_16K] should be configured accordingly.

Address: 4006_C000h base + 40h offset = 4006_C040h

15.4 Functional Description

15.4.1 Power Shutdown Controller

The Power Shutdown Controller takes control once all the clocks are successfully gated and GPC is configured for LPSTOPn modes. It initiates the power down request to Power Gating Controller (PGC) enabling PGC to start the power down sequence. It also monitors wake up request and accordingly generates power up request to PGC after HPREG stablizes. The system can wake-up from the following sources

- External reset
- System wake-up from WKPU
- Level Trigger Interrupt (only for STOP mode)

NOTE

During wake-up by interrupt, software should mask the corresponding interrupt in GPC_IMR register which are not the source of wake-up during STOP mode.

15.4.2 Power Gating Controller

The Power Gating Controller (PGC) is a power management component that controls the power-down and power-up sequencing of individual subsystems. For subsystems to be completely powered down in low power modes, a specific sequence of power control signals must be followed. The sequence timing is programmable using the PGC control registers.

Figure 15-12 shows the PGC as part of the overall power management scheme in this device.

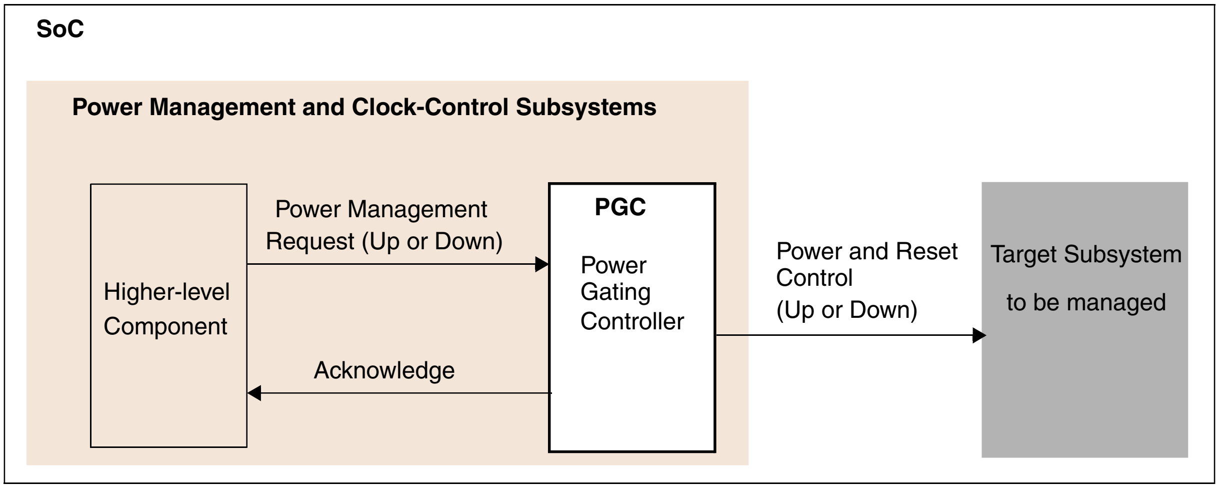

Figure 15-12. PGC Top-Level Block Diagram

15.4.2.1 Functional Mode

The following sections describe the power-control sequencing steps for various low power modes .

15.4.2.1.1 LPSTOP Entry Sequence (PG Entry Sequence)

These steps outline the power-down sequence:

1. Software sets the GPC_PGCR[PG_PD1] bit, see Power Gating Control Register (GPC_PGCR).
2. Software also configures the GPC_LPMR[CLPCR] to STOP mode.

3. CCM stops the clocks to the target subsystem on receiving ARM_DSM_REQUEST after executing WFI instruction.
4. On receiving the stop clock indication from CCM, GPC put the memories into deep sleep if GPC_PGCR[DS_LPSTOP] is set to '1'.
5. GPC asserts *isolation* to isolate the outputs of power-gated domain.
6. GPC triggers SRC to assert reset to power gated domain(PD1) .
7. VREG_DIG then power gated the power domains after 20 μs.
8. VREG_DIG also powered down HPREG and LPREG after 50 μs.
9. FIRC is disabled if CCM_CCR[FIRC_EN] is configured to '0' after VREG_DIG completely power down the regulators.

Figure 15-13 shows the power-down sequence.

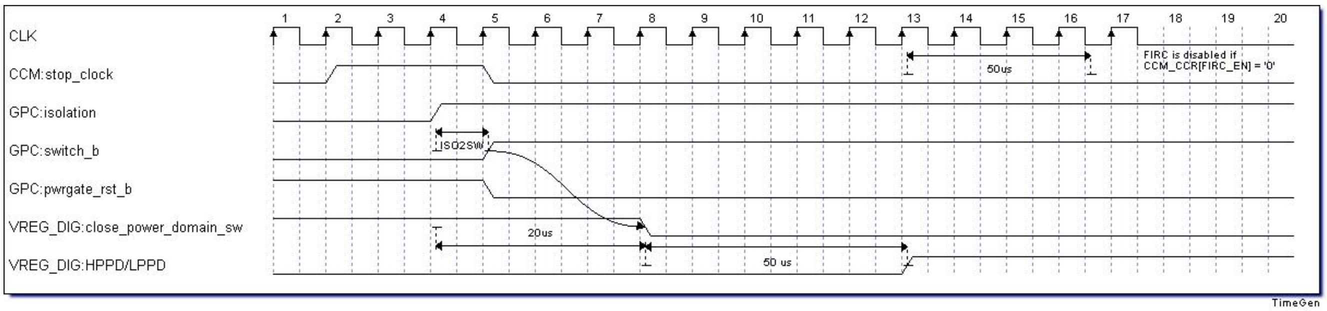

Figure 15-13. Power-Down Sequence Timing Diagram

15.4.2.1.2 LPStop Mode Exit Sequence

The LPStop mode exit sequence is not interruptible and initiated only on receiving system wake up, or external reset.

These steps outline the LPStop exit sequence:

1. On exit, GPC first enables the FIRC and removes the deep sleep synchronously
2. VREG_DIG enables the HPREG and LPREG on receiving wake-up indication from GPC
3. GPC, then enables all the power domain switches after HP regulator stabilizes.
4. GPC indicates SRC to remove the reset from power gated domain once all the power domain switches are closed.
5. GPC negates the isolation after two cycles.
6. CCM then starts enabling the clocks once the isolation is removed.

Figure 15-14 shows the power-up sequence.

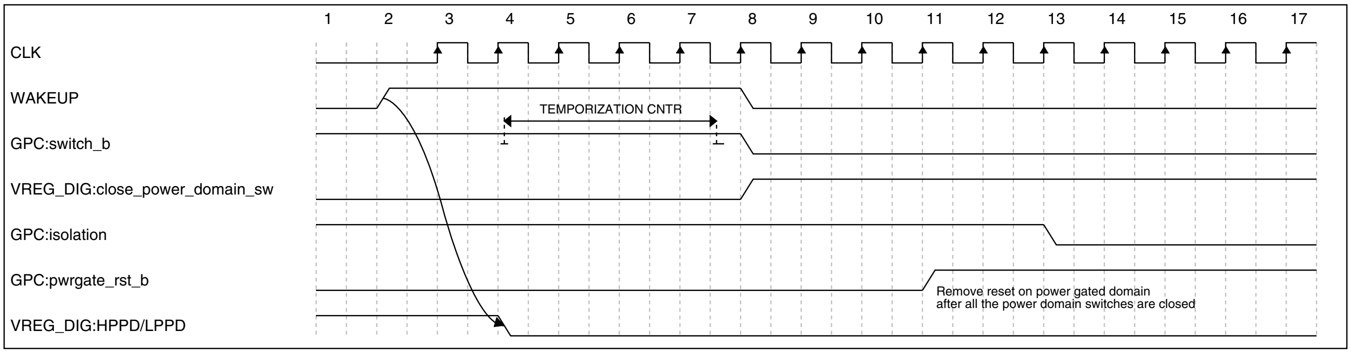

Figure 15-14. Power-Up Sequence Timing Diagram

15.4.2.1.3 Stop Mode Entry Sequence

The following steps outline the normal stop mode entry sequence:

1. Software ensures GPC_PGCR[PG_PD1] bit and GPC_PGCR[WB_STOP] bit are not set; see Power Gating Control Register (GPC_PGCR)
2. Software also configures the GPC_LPMR[CLPCR] to STOP mode.
3. The clock-control subsystem stops the clocks to the target subsystem on receiving ARM_DSM_REQUEST after executing WFI instruction.
4. On receiving stop clock indicating from the CCM, HPREG is power-down and put the memories into deep-sleep based on GPC_PGCR[HP_OFF] and GPC_PGCR[DS_STOP] configurable bit.
5. FIRC is disabled, if CCM_CCR[FIRC_EN] is configured to '0'.

15.4.2.1.4 Stop Mode Exit Sequence

The following steps outline the normal stop mode exit sequence on receiving system wake up, external reset or interrupt which are configured as source of wakeup:

1. The stop-mode exit is initiated by enabling the FIRC oscillator
2. HPREG is enabled synchronously and deep-sleep is removed
3. After the expiry of 10us (configurable through fuse), wakeup is generated to CCM to enable the clocks

15.4.2.1.5 Well Bias Stop mode entry sequence

These steps outline the well bias stop mode sequence:

1. Software ensures GPC_PGCR[PG_PD1] bit is not set and GPC_PGCR[WB_STOP] bit is set; see Power Gating Control Register (GPC_PGCR)
2. Software also configures the GPC_LPMR[CLPCR] to STOP mode.
3. The clock-control subsystem stops the clocks to the target subsystem
4. On receiving stop clock indicating from the CCM, well bias cell are isolated and put the memories in deep sleep based on GPC_PGCR[DS_STOP].

5. PMOS switch is then disabled after 2 clocks
6. After 5us, Well Bias Regulator is enabled.
7. HPREG is powered down after 5 us once the WB regulator is enabled. Also disabled FIRC if CCM_CCR[FIRC_EN] is configured to '0'.

Refer to Voltage Regulators for details.

15.4.2.1.6 Well Bias Stop mode exit sequence

The well bias stop mode exit is initiated on receiving system wake up, or external reset. It also exits from well bias stop mode on interrupts which are configured as source of wake up from stop mode. The following outline the well bias stop mode exit sequence.

1. On well bias stop mode exit indication,GPC enables FIRC oscillator if it was configured to be off.
2. HPREG is then enabled synchronously and deep-sleep is also removed
3. Wakeup is generated to CCM after 300 ns
4. After 5us, Well Bias regulator is disabled
5. PMOS switch is enabled after the expiry of another 5us and then isolation is removed after 2 clocks
6. CCM sampled the wakeup signal once isolation is removed and enabled the clocks henceforth

15.4.2.1.7 Inhibit Stop and FIRC Control

The inhibit stop signal from the platfom prevents the entry into STOP mode. This is possible by overwriting the LPM mode provided to the CCM. During inhibit stop, the LPM mode exposed to CCM is RUN mode irrespective of other mode configured in GPC_LPMR register. The inhibit stop signal is discarded if the GPC is configured for LPSTOP mode (where GPC_LPMR[CLPCR] = 2’b10 and GPC_PGCR[PG_PD1] = 1’b1. See Low Power Mode Register (GPC_LPMR) and Power Gating Control Register (GPC_PGCR)

The FIRC oscillator can be disabled during LPRUN and STOP mode to minimize power. During LPRUN GPC_LPMR[CLPCR = 2'b00], enabling and disabling of FIRC is software controllable through CCM_CCR[FIRC_EN] bit. When GPC_LPMR[CLPCR] is configured to WAIT/STOP mode, FIRC is enabled by default and it gets disabled only after the completion of Low-power mode entry by hardware depending on CCM_CCR[FIRC_EN] configurable bit in CCM. On exit, FIRC is enabled and remained ON until GPC_LPMR[CLPCR] is configured to RUN mode and CCM_CCR[FIRC_EN] is configured to '0'.

Chapter 16
Voltage Regulators

16.1 Overview

The power blocks are used for providing 1.2 V digital supply to the Core logic of this device. The main/input supply voltage is 3.3 V. Digital/regulated output supply is 1.20 V - 1.26 V, for High Power/Run mode. Maximum load current supported is 1200 mA in high power mode. There are two other modes, namely "low power" and "ultra low power" with lower current driving capabilities and lower power consumption to support the device low power modes.

Power management for this device requires the following blocks described below:

- High power regulator HPREG
- Low Power Regulator LPREG
- Ultra Low Power Regulator ULPREG
- 1.1 V Regulator LDO_IP1
- 2.5 V Regulator LDO_2P5
- 3.0 V Regulator USB_LDO
- SNVS Regulator
- Voltage reference for HPREG
- Voltage reference for LPREG, ULPREG, and Low Voltage Detectors (LVD)
- Low Voltage detector for 3.3 V supply
- Separate Low voltage detector for HPREG, LPREG, and ULPREG output voltages
- Separate High voltage detector (HVD) for HPREG
- Power on Reset (POR)

- Power-up sequencing
- N-well Bias circuit, which contains Well Bias Regulator (WBREG), to reduce leakage power in Low Power modes.

The voltage regulator digital interface provides the temporization delay of 300 μs at initial power-up and and during exit from LPSTOP mode. This, in conjunction with POR1 (which means ULPREG is powered-up), indicates the SRC to release the reset to the device and enter to the next phase, i.e, phase1. It provides trimming controls for regulators and LVDs. It also manages transition from run to low power mode and vice-versa. It generates interrupt on High Voltage Detection during RUN and STOP mode.

Various feature of the VREG digital interface are:

- Temporization counter of 300 μs to get HPREG and HPBGAP up and stable during:
  - initial power up
  - LPSTOP mode exit
- Transition between different modes:
  - RUN to STOP
  - RUN to LPSTOP mode
  - STOP to RUN mode
  - LPSTOP to RUN mode
- Source of Power-On-Reset to Sytem Reset Controller.
- Interrupt on HVD (High Voltage Detection) during RUN and STOP mode
- Masking of HVD and HPLVD (High Power Low Voltage Detection) during LPSTOP mode
- Well Bias circuit control during STOP mode

16.1.1 Signal Description

The following signals connect off-chip. VDDREG, VSS, VDD are the Power supplies.

Table 16-1. Signal Description

Signal name	Direction	Description
VDDREG	In/Out	3.3 V supply for regulation

Table continues on the next page...

Table 16-1. Signal Description (continued)

Signal name	Direction	Description
VSS	In/Out	Ground for Supplies
BCTRL	Out	Base control Pin for the external Ballast transistor.
VDD	In/Out	1.2V regulated supply from Ballast transistor.

16.1.2 Digital Interface Block Diagram

The following figure shows the block diagram for Voltage Regulator Digital Interface.

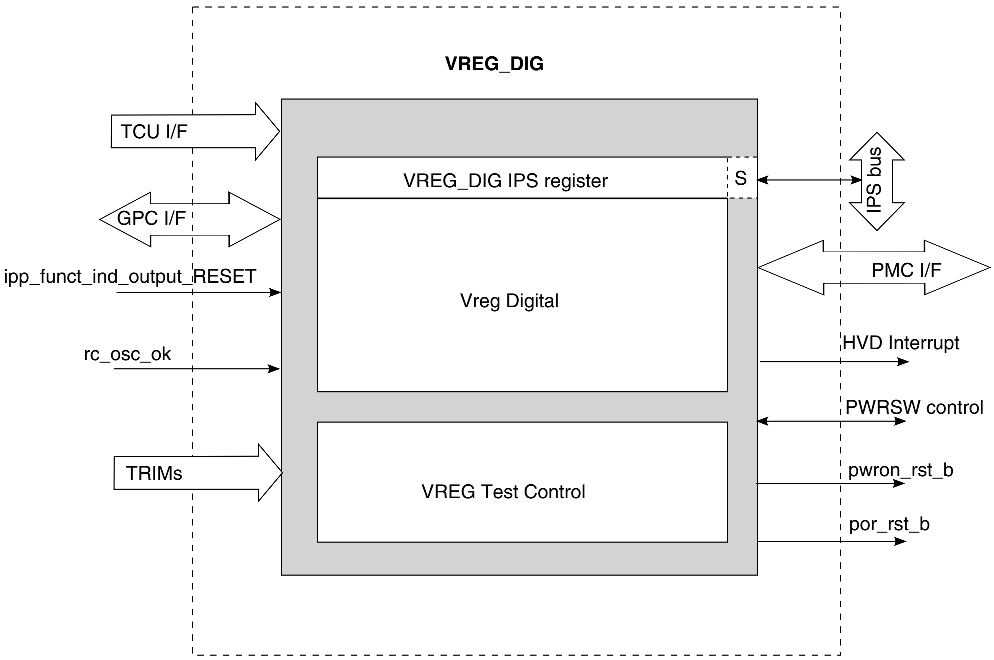

Figure 16-1. VREG_DIG Block Diagram

16.2 Memory Map and Registers

16.2.1 Control Register (VREG_CTRL)

The lower bit (Mask) of this register controls the masking of the HVD interrupt. The reset value of this bit is such that it unmasks the HVD interrupt.

The PORPU bit is used to control PORPU which is an input 1.2V level active high signal of the voltage regulator and is used to disable the POR-LVDMOKHV loop. The signal controls the zero/non-zero current consumption mode of the POR. The signal can control the POR only after LVDMOKHV is high. To save current consumption in low power mode (STOP/LPSTOP), this circuitry can be disabled by driving 0 on PORPU. This will disable the generation of POROUT. Whenever the High Power regulator is switched-off, POROUT circuitry can also be disabled by programming this register bit. This register can be programmed anytime by the software but the affect would only happen when the HPPD to voltage regulator is 1 (that is, HPREG is off). During RUN mode this circuitry is always ON as it does not provide considerable current consumption.The lower bit (Mask) of this register controls the masking of the HVD interrupt. The reset value of this bit is such that it unmasks the HVD interrupt.

Address: 4006_D000h base + 0h offset = 4006_D000h

31–1 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
0 HVDSTAT	This bit status of HVD. It is read only and write 1 to clear. 1 : HVD interrupt is set 0 : HVD interrupt is cleared

16.3 Functional Description

The voltage regulator consists of three internal regulators - HPREG, LPREG and ULPREG. These are designed keeping in mind that when in LPSTOP mode, the HPREG and LPREG are turned off; while in STOP mode, HPREG is turned off. The always-ON design works on ULPREG. In RUN mode, the main current is supplied from HPREG (trimmed at 1.20V) and the LPREG and ULPREG (trimmed at 1.15V) are unloaded.

16.3.1 High Power or Main Regulator (HPREG)

This section describes High Power Regulator (HPREG), which is used to convert 3.3 V input supply (VDDREG) to 1.23 V digital supply. HPREG is split into two parts:

- Regulator Controller
- The NPN bipolar transistor, which is placed external to the chip

The base of the bipolar transistor is driven by a control signal generated by the controller. The nominal target output is 1.23 V typical. The actual output will be in the range of 1.20 V - 1.26 V, post trimming. The stabilization for HPREG is achieved using an external capacitance. The minimum recommended value is 4.7 µF. HPREG gets its reference voltage from a Bandgap reference circuit, which is internal to the module (LPBGAP, with a voltage of 1.2V post trim). This reference voltage is required to be trimmed to reduce the spread of the output supply.

16.3.2 Low Power Regulator (LPREG)

LPREG generates power for the device in STOP mode and has a drive strength of 200mA. The output of this regulator is tied to HPREG and in normal mode it does not supply any load current. The regulator is driven by VDDREG supply and provides the output supply of 1.22V in STOP mode, when HPREG is turned off. It has programmable output voltage in steps of 25mV.

Post trim output is in the range of 1.18 V to 1.24 V.

16.3.3 Ultra Low Power Regulator (ULPREG)

ULPREG generates power for the Low Power Stop modes when both HPREG & LPREG are turned off. Output of this regulator is tied those of HPREG & LPREG, but it does not supply current in normal or STOP mode. It has very low power consumption and has low load and line regulation requirements. It has output voltage programmability, but no offset programmability. Maximum drive current is 20mA.

Internal ballasts are also present in ULPREG.

16.3.4 LVDs and POR

Two types of LVDs are available:

- LVD_MAIN for the 3.3V input supply with upper and lower thresholds at 2.770 V and 2.748 level.
- Three separate LVD_DIG for the 1.2V common output voltage of HPREG, LPREG and ULPREG

The LVD_MAIN is for VPLUSIO supply and provides ULVDMOKHV and ULVDMOKLV as active high signals at 3.3V and 1.2V supply levels, respectively. One LVD_DIG is at HPREG output, one at LPREG and one at output of ULPREG. MLVDDOKHV/LV are active high signals for LVD at HPREG,and ULVDMLPOKHV/LV for LVD at LPREG . LVD_DIG placed in the standby domain at ULPREG output senses the standby ULPVDD supply level. It provides ULVDDOKHV/LV as active high signals. The reference voltage used for all LVDs is from the trimmed LPBGAP. All LVD_DIG can be programmed for different thresholds. Power-down pins are provided for all LVDs.

When LVDs are powered down, their outputs are pulled high. When high power and low power regulators are OFF, the LVD_DIG placed in the main domain should also be in power-down state.

16.3.5 Power Up Sequencing

During supply ramp-up, POR1P2 is used to mask all 1.2V control signals and initialize the LVDOKs to '0' output level. At start-up, all regulators and LVDs are turned ON after 3.3V supply POR3P3 is released. The 1.2V control bit masking is released once:

- POR1P2 is released for 1.2V supply which is after 1.2V supply is stable
- ULVDDOKHV, MLVDDOKHV, and ULVDMOKHV are '1'

During start-up or LPSTOP exit mode, load should be applied only after waiting for a time equal to the start-up time of HPREG. During the normal operation, all of the three regulators HPREG, LPREG and ULPREG will be simultaneously on, but the load current will be supplied by HPREG only. Similarly, when the device enters STOP mode, HPREG will be off, but LPREG and ULPREG will be simultaneously on, and the load current will be supplied by LPREG. During LPSTOP mode, only ULPREG will be on and LPREG and HPREG will be turned off.

The following sections provides the functional information of VREG_DIG and how the voltage regulator should be controlled during various low-power modes.

16.3.6 STOP Mode

When the device is operating in RUN mode, HPREG and LPREG both are ON, but current is supplied by the HPREG. In the Stop mode, device is powered up but there is not much activity (clock) happening inside the device. Therefore, in the Stop mode, LPREG is sufficient to provide the required device current and hence, HPREG is switched off. On system wakeup, it enables the HPREG and switch to RUN mode.

16.3.7 Low Power Stop Mode (LPSTOP)

In LPSTOP mode, a small part of the device is ON and the remaining part is not powered. In this mode, ULPREG supplies the core current (leakage) while HPREG and LPREG is OFF. VREG_DIG also opens all the power switches (PD1, 16K and 48K) based on the configuration provided in GPC power gate control register before powering

off the HPREG and LPREG. On system wakeup, it enables the transition to RUN mode by enabling the HPREG and LPREG. All the power switches are closed after HPREG stabilizes.

16.3.8 Well Bias STOP Mode

It enables the system to enter into lowest power STOP mode. In this mode, the device current is provided by WBREG regulator while HPREG is switched off. On system wakeup, it enables the HPREG and disables the WBREG.

Chapter 17
Reset

17.1 Introduction

This chapter describes the Reset architecture for this device.

17.2 Reset Sources

The possible sources of reset on this device are as follows:

- POR (Power On Reset)
- External hardware reset via the /RESET pin (ext_reset_b pin) - Active Low
- Software JTAG
- Watchdog Reset
- Security Reset (CSU_RESET_B)
- Clock Monitor Reset (CMU). The CMU is used to monitor the main 24MHz crystal oscillator.
- PMU Low Voltage Detection. LVDs on the 3.3V Main supply and the 1.2V core supplies will trigger a reset event. HVDs on the supplies do not trigger a reset but will optionally trigger an interrupt.
- CPU Exception Error Check (illegal opcode or other CPU exception error)

17.3 Reset Functions

The following table shows the action on the SoC of each of the possible reset sources. Although the LDOs do not generate resets they are listed in the table. Only the main PMU can generate a reset based on its LVDs.

The various 'targets' for reset are grouped as follows:

A -> All device Configurations (Trimbits, fuse shadow bits, memory repair registers), Boot configuration & reset vectors, CCM, OCOTP, ANADIG.
B -> SJC, TAP registers
C -> Security Logic
D -> SRTC
E -> DDR Logic
F ->All other logic on SoC

Table 17-1. Reset Functionality

	A	B	D	E	F	
Reset Source	**Configs**	**SJC/TAP**	**RTC**	**DDR Logic**	**All other**	**Comments**
POR	Reset	Reset	Reset	Reset	Reset	Reset all with POR
/RESET	Reset	Reset	No	Reset	Reset	RTC runs through Reset
Software JTAG	Reset	No	No	Reset	Reset	
WDOG	No	No	No	Reset	Reset	
CMU	Reset	Reset	Reset	Reset	Reset	CMU monitors loss of 24MHz XTAL
LVD (PMU)	Reset	Reset	Reset	Reset	Reset	
HVD (PMU)	No	No	No	No	No	Configurable interrupt, no reset
LDO-OK (3.3/1.1-analog)	No	No	No	No	No	Configurable interrupt, no reset
LDO-OK (3.3/2.5-analog)	No	No	No	No	No	Configurable interrupt, no reset
LDO-OK (3.3/1.1-coin)	No	No	No	No	No	No interrupt relevant as only VBat domain alive
LDO-OK (5.0/3.3-USB)	No	No	No	No	No	Configurable interrupt, no reset
CPU Exception	No	No	No	Reset	Reset	

17.4 Clock Monitor

The Clock Monitor Unit (CMU) is used to monitor the main 24MHz crystal oscillator. Upon failure of the crystal the CMU should reset the system.

Chapter 18
System Reset Controller (SRC)

18.1 Introduction

The SRC - System Reset Controller- generates the resets for the whole device. The functional reset sources are programmable as either reset or interrupt. The block also generates interrupts for various device events.

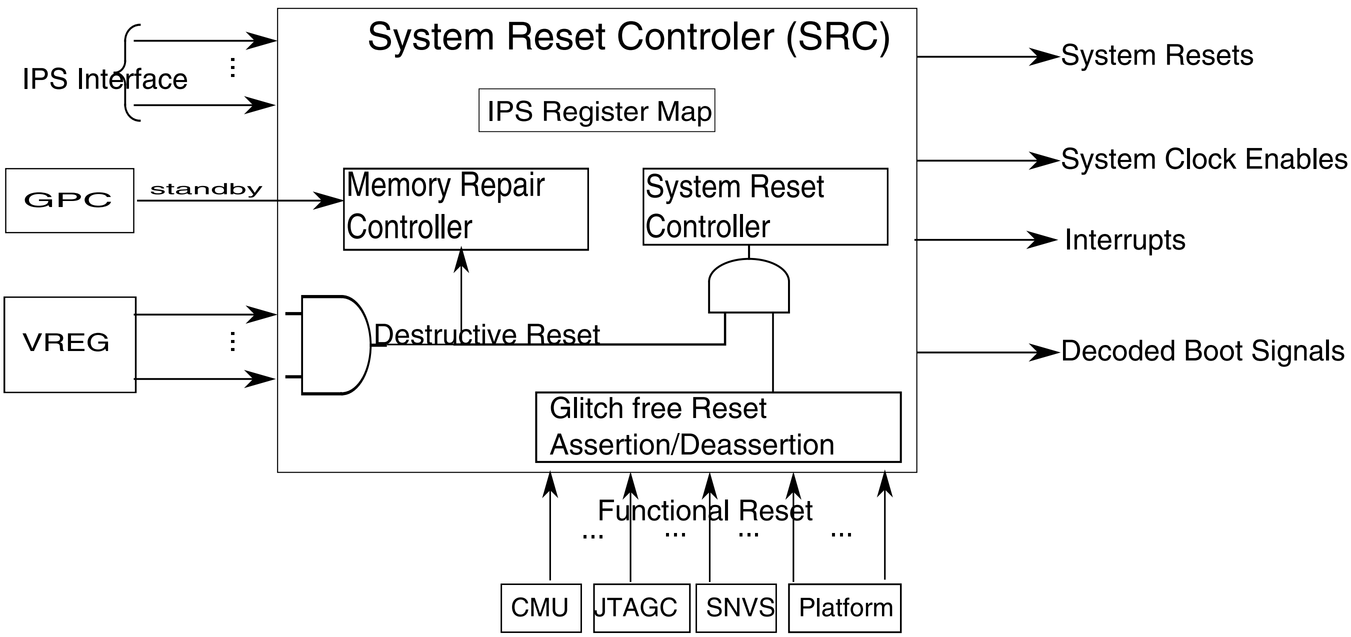

Figure 18-1. Functional reset sequence

18.2 SRC Overview

The system reset controller (SRC) generates all reset signals for the device. The SRC controls the bringup of the device from all of the destructive and functional resets. The SRC handles three types of resets

- Destructive reset: These resets are caused by LVD(s) and poweron reset. It causes the whole device to reset.
- Functional reset: These resets are caused by different events. They cause most of the system to reset except the modules resettable only by destructive reset like SRC, DAP, WDOG, etc.
- Standby reset: This reset is triggered by programming the GPC. The power domain 1 of the system is reset.

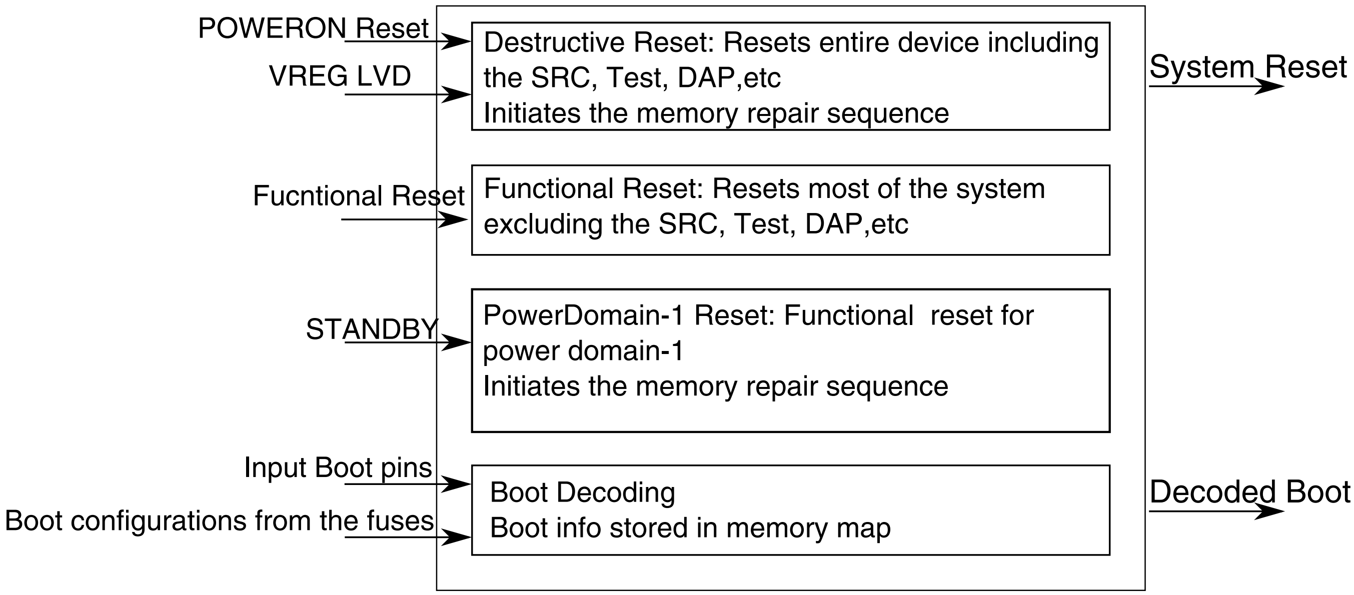

Figure 18-2. SRC High Level Diagram

18.2.1 Features

The SRC includes the following features.

- Receives and handles the resets from all the reset sources
- Resets the appropriate domains based upon the reset sources and the nature of the reset
- Latches the BMOD pins and common configuration signals from the internal fuses
- Provides user flexibilty to choose the events as functional reset or interrupt
- Latches all reset/interrupt events in the SRC_SRSR

18.3 Memory Map and Register Definition

18.3.1 Register Descriptions

This section consists of register descriptions in address order. All registers are reset on POR sequence.

SRC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4006_E000	SRC Control Register (SRC_SCR)	32	R/W	0000_050Ah	18.3.2/792

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0			0	0	CM4_WDGRST_MASK				0			CA5_WDGRST_MASK			
W				SW_RST												
Reset	0	0	0	0	0	1	0	1	0	0	0	0	1	0	1	0

SRC_SCR field descriptions

Field	Description
31–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12 SW_RST	Software reset. Initiates Functional reset sequence 0 Software reset not requested 1 Software reset requested Self clearing, Always read 0
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–7 CM4_WDGRST_ MASK	Mask wdog_rst_b of CM4 core. If these 4 bits are coded from A to 5 ,then wdog_rst_b input to SRC will be masked and wdog_rst_b will not create reset to the device. Any other code will be coded to 1010 that is wdog_rst_b is not masked. 0101 wdog_rst_b is masked 1010 wdog_rst_b is not masked (default) Write of anyvalue other than 01010 will set the field to 1010
6–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–0 CA5_WDGRST_ MASK	Mask wdog_rst_b of CA5 source. If these 4 bits are coded from A to 5 then, wdog_rst_b input to SRC will be masked and wdog_rst_b will not create reset to the IC. 0101 wdog_rst_b is masked 1010 wdog_rst_b is not masked (default) any other code will be coded to 1010 i.e. wdog_rst_b is not masked **NOTE:** During the time the WDOG event is masked using SRC logic, it is likely that WDOG Reset Status Register (WRSR) bit 1 (which indicates WDOG timeout event) will get asserted. SW / OS developer must prepare for this case. Re-enable WDOG is possible, by un-mask it in SRC, though it must be preceded by servicing the WDOG. However, for the case that the event has been asserted, the status bit (WRSR bit-1) will remain asserted, regardless of servicing the WDOG module. (HW reset is the only mean to cause de-assertion of that bit).

Table continues on the next page...

SRC_SCR field descriptions (continued)

Field	Description
	0101 wdog_rst_b is masked 1010 wdog_rst_b is not masked (default)

18.3.3 SRC Boot Mode Register 1 (SRC_SBMR1)

The following presents the Boot Mode register (SBMR1), which contains bits that reflect the status of Boot Mode Pins of the chip. The default values for those bits depend on the values of pins/fuses during reset sequence.The boot configuration signals are sampled once fuses are read. The boot configuration can either be sampled from OCOTP or GPIO based on the boot mode selected. The table provides its field descriptions.

NOTE

When sampled from GPIO, these bits are only updated on a Power On Reset (POR).

Address: 4006_E000h base + 4h offset = 4006_E004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	BOOT_CFG4								BOOT_CFG3

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SRC_SBMR1 field descriptions

Field	Description
31–24 BOOT_CFG4	Please refer to OCOTP_CFG4 .
23–16 BOOT_CFG3	Please refer to OCOTP_CFG3 .
15–8 BOOT_CFG2	Please refer to OCOTP_CFG2 .
7–0 BOOT_CFG1	Please refer to OCOTP_CFG1 .

18.3.4 SRC Status Register (SRC_SRSR)

The SRSR is a status register that records the source of the reset events for the chip. The SRSR register bit is set when the event occurs.

NOTE

On a Power on Reset, the register will read 0x00FEFF65. The recommendation is to clear all reset sources after a POR event to read the proper reset status for future reset events.

NOTE

When using a debugger, the RESETB bit will also be set due to the debugger asserting reset.

NOTE

The following bits are expected to be valid after a power on reset.

- SRSR[POR_RST]
- SRSR[CA5_WDG_RST]
- SRSR[WDOG_RST]
- SRSR[RESET_B] - due to debugger
- SRSR[POR1P2]
- SRSR[HP_LVD]
- SRSR[ULP_LVD]
- SRSR[LVD_P3P]
- SRSR[LP_LVD]
- SRSR[MDM_SYS_RST]

At bootup the SW can mask-read all the other SRSR bits i.e. ignore other bits. All bits should be cleared by writing '1' to them after bootup for proper status setting.

Address: 4006_E000h base + 8h offset = 4006_E008h

SRC_SECR field descriptions

Field	Description
31–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4 WRLOCK	Once writeable. Once written the SPIDEN and SPNIDEN can't be written
3–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 SPIDEN	Secure invasive debug enable. Can be set by user running device in secure mode. Refer to Additional Authentication Interface
0 SPNIDEN	Secure non-invasive debug enable. Can be set by user running device in secure mode.

18.3.6 SRC Reset Interrupt Configuration Register (SRC_SICR)

The SICR is a reset event configuration register. The event mentioned in the bitfield is configured as interrupt, when field is '1' and as reset when the bitfield value is '0'.

Address: 4006_E000h base + 14h offset = 4006_E014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

6 RESERVED	This field is reserved. Reserved for future use
5 JTAG_RST	Configures HIGH-Z JTAG event 1 The bitfield is configured as interrupt 0 The bitfield is reset.
4–3 WDOG_RST	Configures watchdog Time-out event. WDOG_RST_F[1] - CM4 core WDOG_RST_F[0] - CA5 core 1 The bitfield is configured as interrupt 0 The bitfield is reset.
2 RESERVED	This field is reserved. Reserved for future use
1 CA5_WDG_RST	Configures event from internal CA5 watchdog timer 1 The bitfield is configured as interrupt 0 The bitfield is reset.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

18.3.7 SRC Interrupt Masking Register (SRC_SIMR)

The SIMR is a interrupt masking register. The event configured in the SCR_SICR as interrupt can be masked in this register. Once the interrupt is masked it will not reflect in SCR_SRSR. Interrupts are masked when the bitfield representing the event is '0'.

Address: 4006_E000h base + 18h offset = 4006_E018h

18.4 Functional Description

18.4.1 Reset Sources

The Reset control logic receives event requests from all the potential reset sources. All the "functional Reset/ Interrupt" events are qualified based on the SRC_SICR either as interrupt or reset. All the events are latched in the SRC_SRSR register unless masked by SRC_SIMR register. The reset sources are described in the following table.

Table 18-19. Reset_Table

Reset Source	Reset Type
POR1 - power on reset	Destructive reset
POR1P2: 1.2V supply goes below 0.7V event	Destructive reset
HP LVD: HP regulator's LVD event	Destructive reset
ULP LVD: ULP regulator's LVD event	Destructive reset

Table continues on the next page...

Table 18-19. Reset_Table (continued)

Reset Source	Reset Type
LVD_P3P: 3.3V main supply is unstable	Destructive reset
LP_LVD: LP regulator's LVD event	Destructive reset
CA5 internal WDOG Time-out	Functional Reset / Interrupt
Platform WDOG[CA5 core] Time out	Functional Reset / Interrupt
Platform WDOG[CM4 core] Time out	Functional Reset / Interrupt
JTAGC Reset	Functional Reset / Interrupt
External Reset, RESETB	Functional reset
MDM_AP_CTRL[SYSRESETREQ]	Functional Reset / Interrupt
SNVS_HP: Hard Fail state	Default reset.Generated from SNVS_HP
SRC_SCR[SW_RST]	Functional Reset / Interrupt
CSU Alram reset	Functional Reset / Interrupt
Anadig1.1V regulator unstable	Functional Reset / Interrupt
Anadig 2.5V regulator unstable	Functional Reset / Interrupt
Anadig 3.3V regulator unstable	Functional Reset / Interrupt
CMU: FOSC frequency is < 24MHz	Functional Reset / Interrupt
CMU: Bus frequency clock out of range	Functional Reset / Interrupt
No FOSC clock	Functional Reset / Interrupt
No SOSC clock	Functional Reset / Interrupt
CM4 is in lockup	Functional Reset / Interrupt

- If a destructive reset occurs during a functional reset deassertion sequence, the destructive reset sequence will start without completing the current reset sequence
- If a functional reset occurs during a functional reset deassertion sequence. The reset sequence will will re-initiate
- Reset deassertion sequence won't start until all the resets are deasserted

18.4.2 Destructive reset sequence

The resets from SRC to device are asserted immediately on any destructive reset event. While the clock enables are deasserted at the same time. The RESETB is deasserted to indicate that the device is under reset. The memory repair is initiated only after the CCM indicates that all the clocks are enabled.

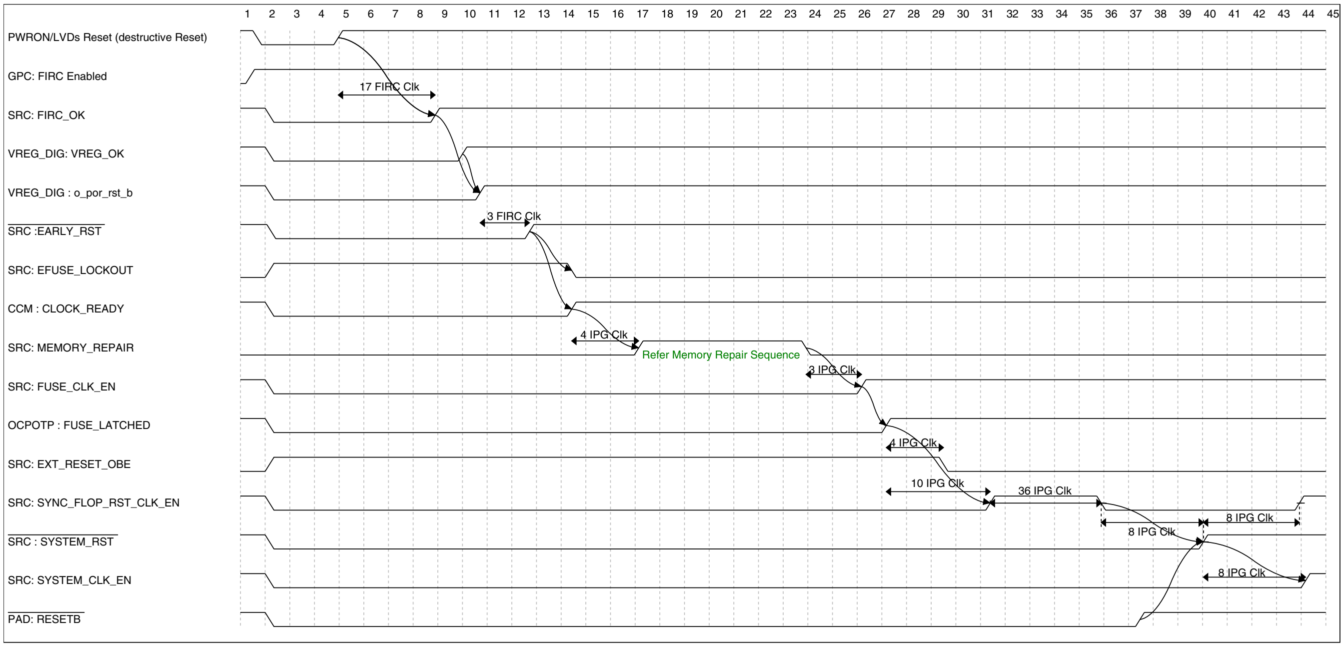

Figure 18-20. Destructive reset sequence

The SRC follows the sequence below on deassertion of poweron or any LVD resets :

1. The stable VREG and FIRC is indicated by VREG by de-asserting the o_por_rst_b.
2. The deassertion of EARLY_RESET wakes the CCM and the OCOTP.
3. Once the CCM indicates that the clocks are stable by asserting the CLOCK_READY the memory repair is initiated.
4. After the memory repair is over the fuses clock is enabled for latching fuses.
5. The latched fuses are decoded by SRC and stored in internal registers.
6. The SYNC_FLOP_RST_CLK_EN is asserted to enable clocks to initialize all non-resetable flops in the device.
7. The deassertion of system reset is held till the external reset RESETB is not released. this is to give controllability to the user on the boot up of the core.
8. The clocks are enabled after the system reset is deasserted, to ensure proper reset recovery

18.4.3 Functional reset sequence

On the assertion of the functional reset the clocks are gated on the edge of the IPG clock to ensure glitch free stop of ongoing transactions. The SRC resets are asserted after the clocks are gated. The RESETB is deasserted to indicate that the device is under reset. The memory repair is not initiated.

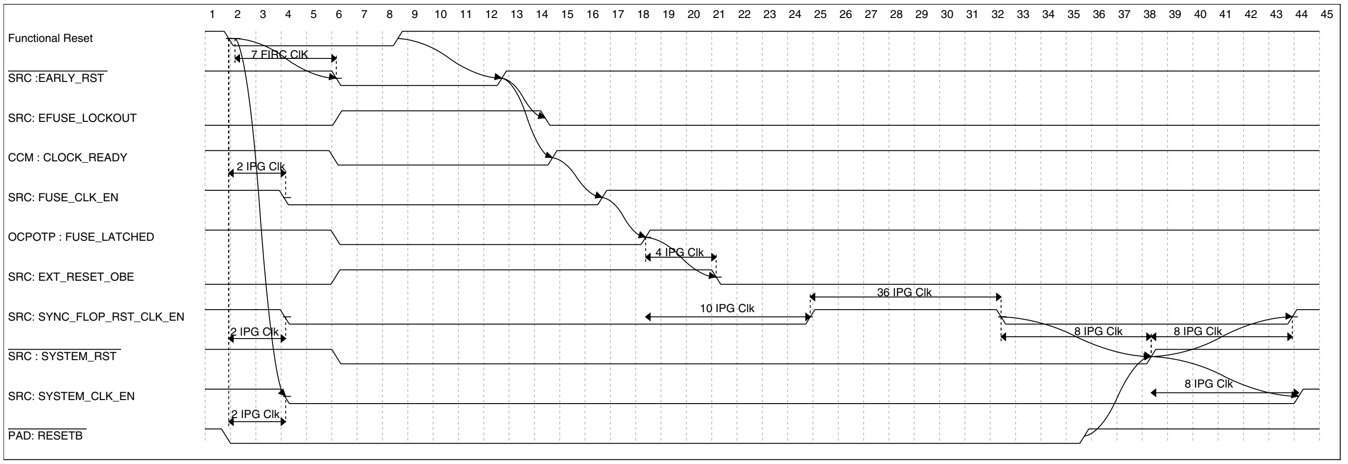

Figure 18-21. Functional reset sequence

The SRC follows the below mentioned sequence on deassertion of any functional reset:

1. The clock enables are deasserted on IPG clock.
2. The SRC resets are asserted after a few FIRC clocks to ensure all clocks are properly gated.
3. The deassertion of EARLY_RESET wakes the CCM and the OCOTP.
4. Once the CCM indicates that the clocks are stable by asserting the CLOCK_READY the clock for the fuse latching is enabled.
5. The latched fuses are decoded by SRC and stored in internal registers.
6. The SYNC_FLOP_RST_CLK_EN is asserted to enable clocks to initialize all non-resetable flops in the device.
7. The deassertion of system reset is held till the external reset RESETB is not released. This is to give controllability to the user on the boot up of the core.
8. The clocks are enabled after the system reset is deasserted, to ensure proper reset recovery.

18.4.4 External reset sequence

On the assertion of the RESETB the clocks are gated on the edge of the IPG clock to ensure glitch free stop of ongoing transactions. The SRC resets are asserted after the clocks are gated. The memory repair is not initiated.

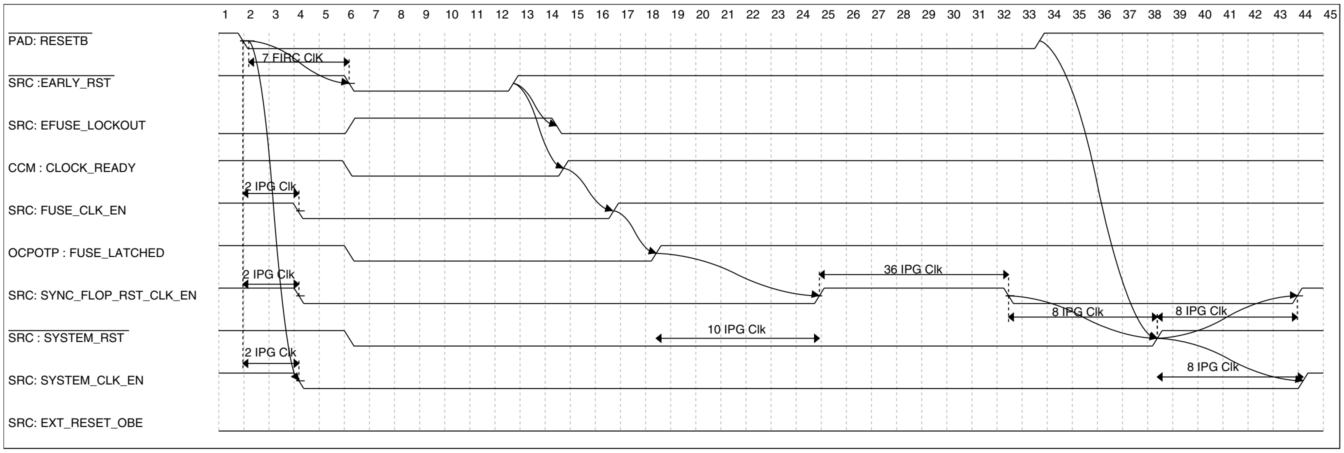

Figure 18-22. External reset sequence

The SRC follows the sequence below on assertion of the external reset, RESETB :

1. The clock enables are deasserted on IPG clock.
2. The SRC resets are asserted after a few FIRC clocks to ensure all clocks are properly gated.
3. The deassertion of EARLY_RESET wakes the CCM and the OCOTP.
4. Once the CCM indicates that the clocks are stable by asserting the CLOCK_READY the clock for the fuse latching is enabled.
5. The latched fuses are decoded by SRC and stored in internal registers.
6. The SYNC_FLOP_RST_CLK_EN is asserted to enable clocks to initialize all non-resetable flops in the device.
7. The deassertion of system reset is held till the external reset RESETB is not released. This is to give controllability to the user on the boot up of the core.
8. The clocks are enabled after the system reset is deasserted, to ensure proper reset recovery.

18.4.5 Standby reset sequence

The Standby reset is asserted after the isolation is activated. On assertion of the standby reset all the clocks are gated and power domain 1 resets are asserted immediately. The memory repair is initiated on exit of Standby.

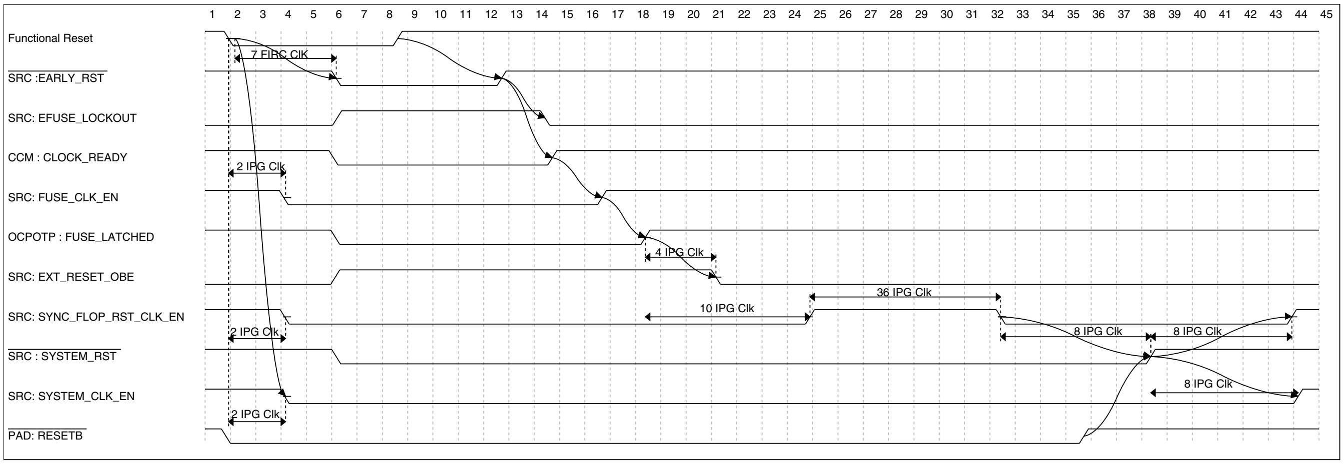

Figure 18-23. Standby reset sequence (Exit by Standby Exit)

The SRC follows the below mentioned sequence on assertion of standby reset :

1. The clocks are gated immediately.
2. The SRC power domain 1 resets are asserted immediately.
3. The deassertion of EARLY_RESET wakes the CCM and the OCOTP
4. Once the CCM indicates that the clocks are stable by asserting the CLOCK_READY, initiating the memory repair sequence.
5. The clock for the fuse latching is enabled after the memory repair.
6. The latched fuses are decoded by SRC and stored in internal registers.
7. The SYNC_FLOP_RST_CLK_EN is asserted to enable clocks to initialize all non-resetable flops in the device.
8. The clocks are enabled after the system reset is deasserted, to ensure proper reset recovery.

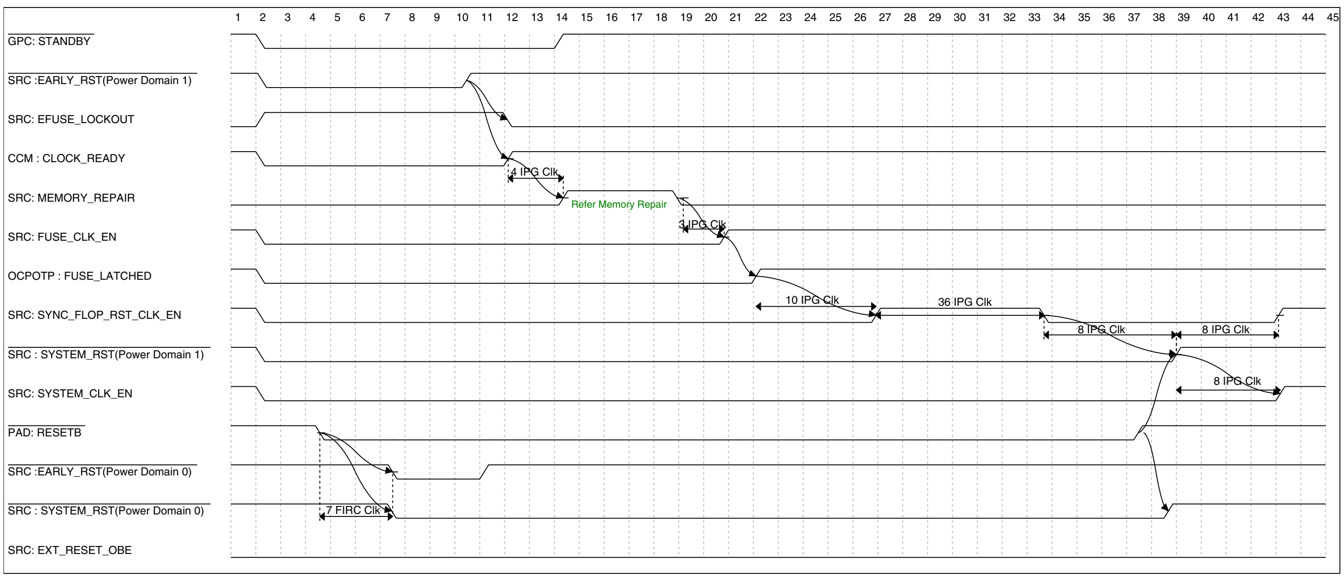

Figure 18-24. Standby reset sequence (Abort by External Reset)

The SRC follows the below mentioned sequence on assertion of standby reset :

1. The clock enables are deasserted immediately.
2. The SRC power domain 1 resets are asserted immediately.
3. The SRC power domain 0 resets are asserted on the assertion of external reset, RESETB. The standby mode is exited.
4. The deassertion of EARLY_RESET wakes the CCM and the OCOTP.
5. Once the CCM indicates that the clocks are stable by asserting the CLOCK_READY, initiating the memory repair sequence.
6. The clock for the fuse latching is enabled after the memory repair.
7. The latched fuses are decoded by SRC and stored in internal registers.
8. The SYNC_FLOP_RST_CLK_EN is asserted to enable clocks to initialize all non-resetable flops in the device.
9. The deassertion of system reset is held till the external reset RESETB is not released. This is to give controllability to the user on the boot up of the core.
10. The clocks are enabled after the system reset is deasserted, to ensure proper reset recovery.

18.4.6 Memory Repair

The memory repair is done after every powerdown of Memory. The two triggering reset events are destructive reset and Standby. The memory repair is initiated after CCM indicates the clocks are stable. The memory repair can be bypassed by assertion signal.

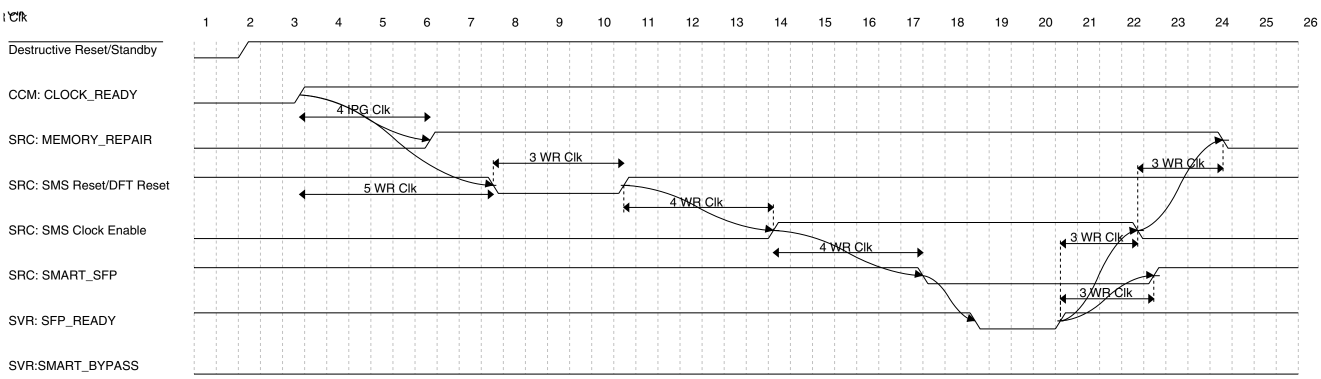

Figure 18-25. Memory Repair Sequence (Bypass ='0')

The memory repair follows the following sequence when SMART_BYPASS ='0' :

1. The memory repair is initiated after the CCM indicates the clocks are ready.
2. The SMS reset are asserted for few memory repair clock cycles.
3. Once the SMS resets are deasserted the memory repair clocks are enabled, for proper clean reset recovery.

4. The SMART_SFP is deasserted.
5. On the assertion of SFP_READY, the SMART_SFP is asserted.
6. The memory repair clock enables are deasserted along with the MEMORY_REPAIR indicator.

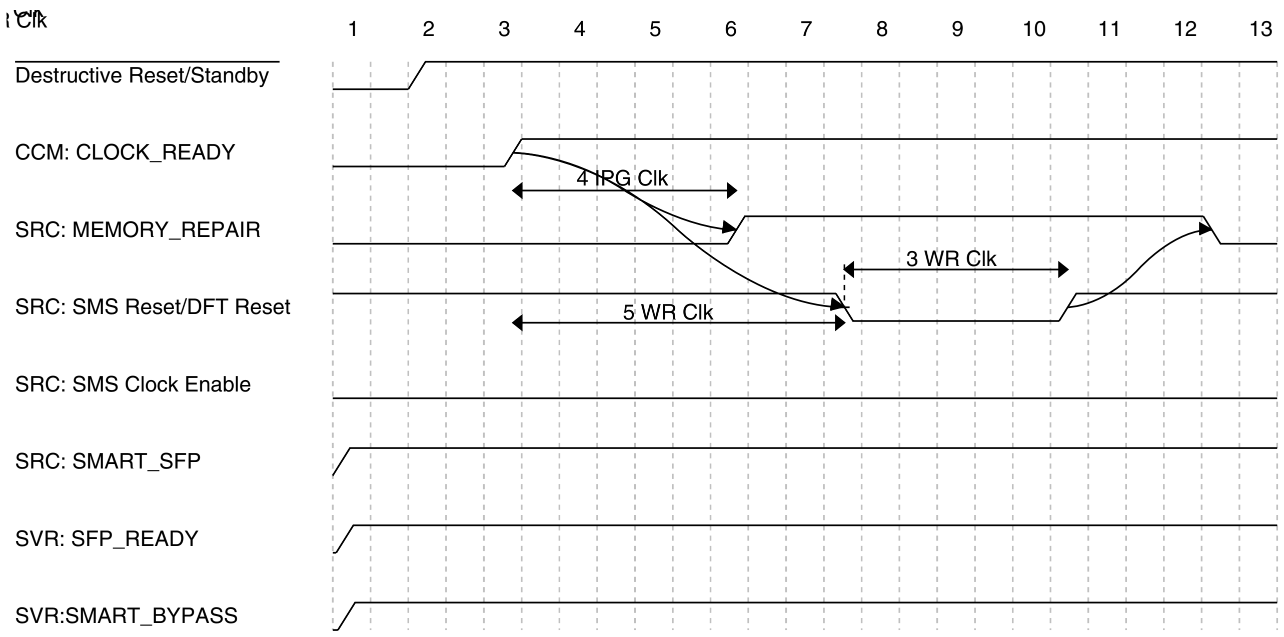

Figure 18-26. Memory Repair Sequence (Bypass ='1')

The memory repair follows following sequence when SMART_BYPASS ='1' :

1. The memory repair is initiated after the CCM indicates the clocks are ready.
2. The SMS reset are asserted for few memory repair clock cycles.
3. The SMS resets are deasserted along with the MEMORY_REPAIR indicator.

18.4.7 BOOTMOD Pin Latching

The exact boot sequence is controlled by the values of the BOOTMOD pins on this device.

All the boot pins will be sampled at deassertion of system_early_rst_b.

The value of the BOOTMOD pins will be latched after the IIM asserts the fuse read completion flag. After latching, the values of the BOOTMOD pins are used to determine the booting options of the core as given in the SBMR register.

The Boot mode general purpose bits can be provided to the SRC from either e-fuses or GPIO signals. The gpio_bt_sel e-fuse defines the source to be used to derive the boot information. When gpio_bt_sel is set, e-fuses are used. When cleared, GPIO signals are used.

When FSL test mode is chosen (11 for BOOTMOD[1:0]) then the GPIO signals are used.

When Internal Production Boot Mode is chosen (00 for BOOTMOD[1:0]) then e-fuses signals are used, independent of the gpio_bt_sel e-fuse value.

The Boot information is provided in SBMR register. The figure below shows the selection of Boot mode information.

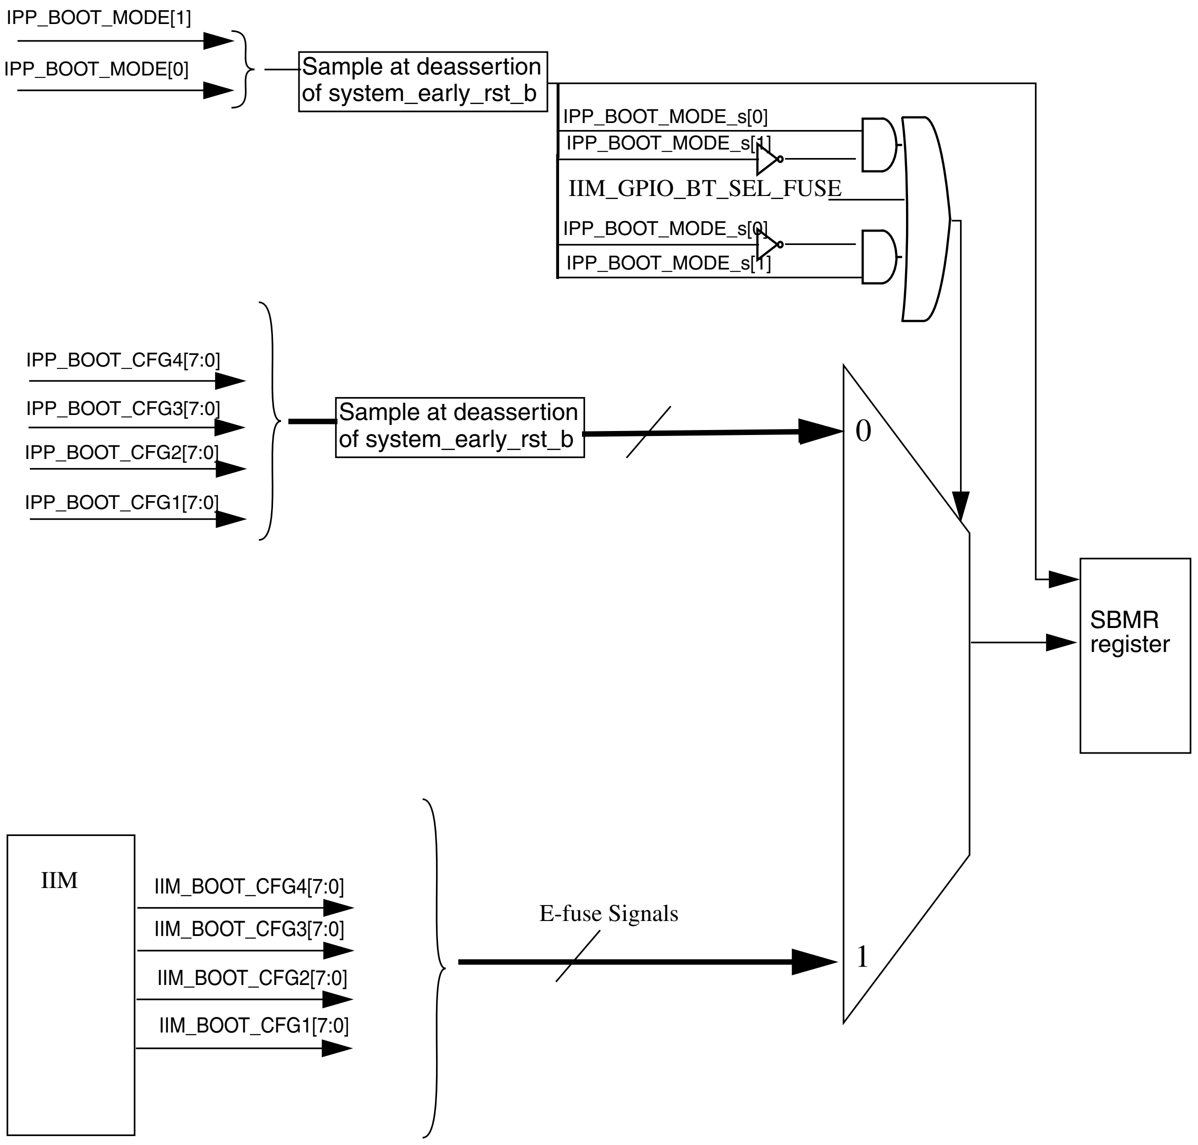

Figure 18-27. Boot Mode Information

Chapter 19
System Boot

19.1 Introduction

The boot process begins at Power On Reset (POR) where the hardware reset logic forces the ARM core to begin execution starting from the on-chip Boot ROM. The Boot ROM code uses the state of the internal register BOOT_MODE [1:0] as well as the state of various eFUSEs and/or GPIO settings to determine the boot flow behavior of the device.

The main features of the ROM include:

- Support for booting from various boot devices
- Serial Downloader support (USB and UART)
- Device Configuration Data (DCD)
- Wakeup from low-power modes
- Wakeup secondary core
- HAB Re-authentication on Low Power Standby exit

Boot ROM supports the following boot devices:

- NOR Flash
- NAND Flash
- FlexCAN
- SD/MMC
- QuadSPI
- Serial ROM devices (through I2C and SPI interfaces)

The boot process can be summarized in the following steps.

1. Reset.
2. Begin execution of Boot ROM code. The boot process depends on the reset type, HAB_REAUTH setting, CPU ID, BOOT_MODE[1:0], and the RCON register.
3. Read the Image Vector Table and boot data structures. Optionally, download image to memory.
4. Execute image, i.e., the user code.

In normal operation, the Boot ROM uses the state of the BOOT_MODE register and eFUSEs to determine the boot device. For development purposes, there is also an option to use GPIO pin inputs to override the fuse values to determine the boot device.

NOTE

BOOT_MODE and and GPIO Pins are sampled on a Power On Reset event.

The Boot ROM code also allows for programs to be downloaded and executed on the device. An example is a provisioning program that can make further use of the serial connection to program a boot device with a new image. Typically, the provisioning program is downloaded to internal RAM and programs the boot devices such as a NAND Flash. The ROM Serial Downloader can use either the high speed USB or UART interface in non-stream mode connection.

The Boot ROM allows waking from low power modes and waking up secondary core (either Cortex-A5 or Cortex-M4 depending on configuration). On reset the Boot ROM checks the CPU ID and power gating status register. The primary core (with ID = 0), on waking up from low power mode, and, secondary core (with ID=1) in all power modes, will skip downloading the image from the boot device. It will jump to the address saved in the PERSISTENT_ENTRY Persistent Bits register.

The Device Configuration Data (DCD) feature allows the Boot ROM code to obtain system configuration data from an external Program Image residing on the boot device. As an example, the DCD can be used to program the SDRAM controller for optimal settings to improve the boot performance. DCD configuration options are restricted to memory areas and peripheral addresses that are considered essential for boot purposes.

The remainder of this chapter provides the details on how to configure and use the boot features of the device.

19.2 Boot Modes

On reset, the device checks the CPU ID in the MSCM CPxNUM register and Power Gating Controller status register.

On normal boot, the Primary Core behavior is defined by the Boot Mode pins settings as described in Boot Mode Pin Settings. On waking up from low power boot mode, the Primary Core skips configuring the clocks. The Boot ROM checks that PERSISTENT_ENTRY0 (see Persistent Bits) is a pointer to a valid address space (internal SRAM, DDR, FlexBus, and QuadSPI). If PERSISTENT_ENTRY0 is a pointer to a valid range, it starts execution using the entry point from the PERSISTENT_ENTRY0 register. If PERSISTENT_ENTRY0 is a pointer to an invalid range, the Primary Core performs a system reset.

Note

Wake-up from Internal SRAM is only supported as clocks to other modules are disabled.

For the Secondary Core, the Boot ROM checks that the PERSISTENT_ENTRY is a pointer to a valid address space (Internal SRAM, DDR, FlexBus, and QuadSPI). If PERSISTENT_ENTRY is a pointer to a valid range, it starts execution using the entry point from the PERSISTENT_ENTRY register. If PERSISTENT_ENTRY is a pointer to invalid range, it sets error status registers (see Persistent Bits), sends a wakeup error interrupt, and performs a Wait-For-Interrupt instruction. The Interrupt Service routine of primary core must reconfigure the system and reset the secondary core.

Note

SW that enables secondary core is not part of ROM. It must be part of upper level SW.

19.2.1 Boot Mode Pin Settings

The device has four boot modes (one is reserved for Freescale use). Boot mode is selected based on the binary value stored in the internal BOOT_MODE register. BOOT_MODE is initialized by sampling the BOOT_MODE0 and BOOT_MODE1 pins on the rising edge of RESET_B after POR. After these pins are sampled, their subsequent state does not affect the contents of the BOOT_MODE internal register. The state of the internal BOOT_MODE register may be read from the BMOD[1:0] field of the SRC Boot Mode Register (SRC_SBMR2). The available boot modes are: Boot From Fuses, serial boot via USB or UART, Boot from RCON and FSL Test mode. See the table below for settings.

Table 19-1. Boot MODE Pin Settings

BOOT_MODE[1:0]	Boot Type
00	Boot From Fuses

Table continues on the next page...

Table 19-1. Boot MODE Pin Settings (continued)

BOOT_MODE[1:0]	Boot Type
01	Serial Downloader
10	Boot from RCON

19.2.2 High Level Boot Sequence

The figure below shows the High Level boot ROM code flow in this device.

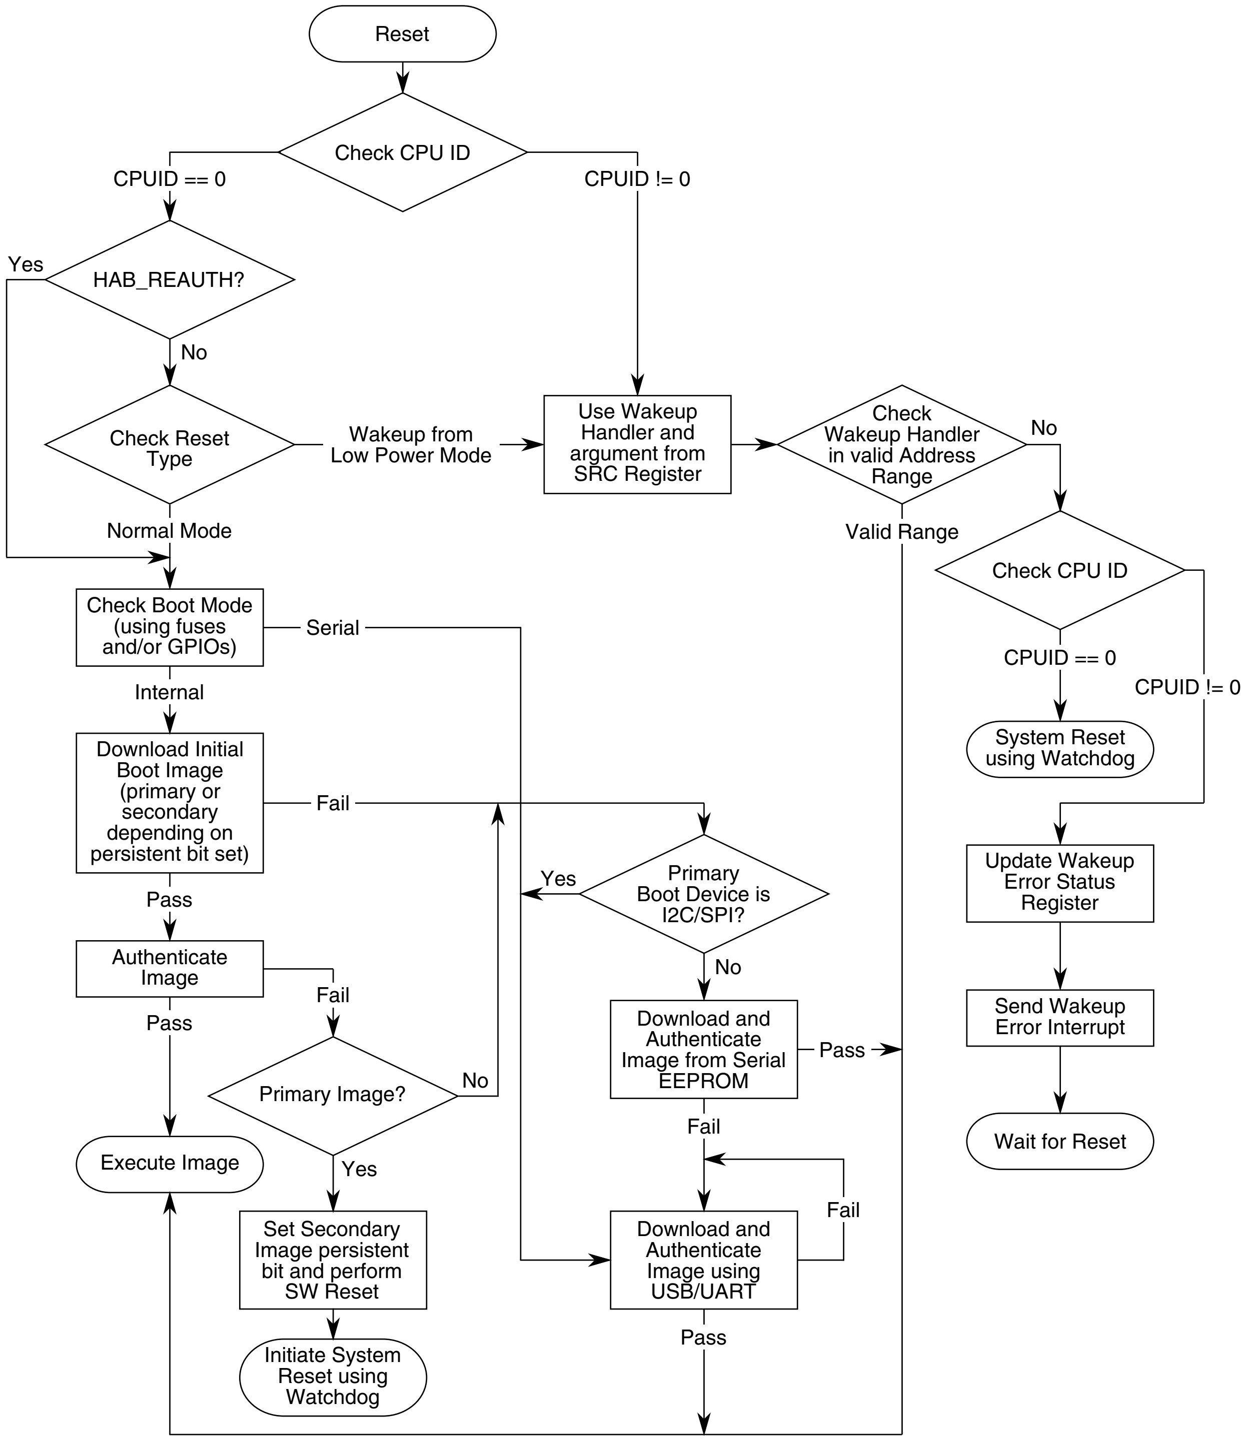

Figure 19-1. BOOT Flow

Note

For FlexBus (NOR) and QuadSPI boot devices, downloading initial load region to iRAM is skipped. IVT is read from FlexBus/QuadSPI address space respectively (see Image Vector

Table and Boot Data). Copying initial load region and the rest of the program image is done only if the absolute start address of the image is not equal to FlexBus/QuadSPI start address.

19.2.3 Boot From Fuses Mode (BOOT_MODE [1:0] = 0b00)

A value of 0b00 in the BOOT_MODE [1:0] register selects the Boot From Fuses mode. This mode is similar to the Boot from RCON mode, with one difference. In this mode the GPIO boot override pins are ignored. The boot ROM code uses the boot eFUSE settings only. This mode also supports a secure boot using HAB.

If set to Boot From Fuses, the boot flow is controlled by the BT_FUSE_SEL eFUSE value. If BT_FUSE_SEL = 0, indicating that the boot device (for example, Flash, SD/MMC) has not yet been programmed, the boot flow jumps directly to the Serial Downloader. If BT_FUSE_SEL = 1, then the normal boot flow is followed, where the ROM attempts to boot from the selected boot device.

The first time a board is used, the default eFUSEs may be configured incorrectly for the hardware on the platform. In such a case, the Boot ROM code may try to boot from a device that does not exist. This may cause an electrical/logic violation on some pads. Using Boot From Fuses mode solves this problem. The first time the BT_FUSE_SEL eFuse is encountered, it is not blown (thus BT_FUSE_SEL=0). This forces the ROM code to jump directly to the Serial Downloader. This allows a bootloader to be downloaded, which can then provision the boot device with a Program Image, and blow the BT_FUSE_SEL and the other boot configuration eFUSEs. After reset, the Boot ROM code determines that BT_FUSE_SEL is blown (BT_FUSE_SEL = 1) and the ROM code performs internal boot according to the new eFUSE settings. This allows a user to set BOOT_MODE [1:0] =0b00 on a production device and burn fuses on the same device (by forcing entry to the Serial Downloader), without changing the value of BOOT_MODE [1:0] or pull-ups/pull-downs on the BOOT_MODE pins.

19.2.4 Mode: Serial Downloader Mode (BOOT_MODE [1:0] = 0b01)

The serial downloader is invoked if the external Flash device is not programmed, when a failure is encountered during the boot flow process, or any of the following conditions are met:

- BOOT_MODE[1:0] = 0b01 (serial downloader mode)
- BOOT_MODE[1:0] = 0b00 (boot from fuses) and the eFUSE BT_FUSE_SEL = 0

- BOOT_MODE[1:0] = 0b00 or 0b10 (Boot From Fuses or Boot From RCON) and there is not a valid image in the external boot
- Internal failure
- Runtime exception occurs
- Error is returned by the HAB functions while in a Closed security configuration. Errors are ignored in an Open security configuration (see Boot Security Settings).

To determine the USB/UART connection, the Boot ROM polls the USB/UART status register.

If WDOG_ENABLE eFUSE is 1 and there is no activity on USB/UART port within the predefined polling time, then the ROM program will power down the SoC using the Watchdog Timer (either WDOG-A5 or WDOG-M4 depending on the primary core). When the serial bootloader is active, the Watchdog is serviced periodically. If the communication between the serial Host and this device is idle for more than 90 seconds, or the processor goes into an endless loop, then the watchdog expires and powers down the device. For details on the Serial Downloader see Serial Downloader (BOOT_MODE [1:0] = 0b01).

19.2.5 Boot from RCON (BOOT_MODE [1:0] = 0b10)

A value of 10 in the BOOT_MODE [1:0] register selects the Boot from RCON. In this mode, the processor continues to execute boot code from the internal boot ROM. The boot code performs hardware initialization, loads the Program Image from the chosen boot device, performs image validation using the HAB library (see Boot Security Settings), and then jumps to an address derived from the Program Image. If any error occurs during internal boot, the boot code jumps to the Serial Downloader (see Serial Downloader (BOOT_MODE [1:0] = 0b01)). A secure boot using the HAB is possible in all the three boot modes.

When set to Boot from RCON, the boot flow may be controlled by a combination of eFUSE settings with an option of overriding the fuse settings using GPIO General Purpose I/O (GPIO) pins. Whether the ROM uses GPIO pins for a select number of configuration parameters or eFUSEs in this mode is determined by the GPIO Boot Select (BT_FUSE_SEL) eFUSE.

- If BT_FUSE_SEL = 1, all boot options are controlled by the eFUSEs described in Table 19-2.
- If BT_FUSE_SEL = 0, specific boot configuration parameters may be set using GPIO pins rather than eFUSEs. The fuses that can be overridden when in this mode are indicated in the GPIO column of Table 19-2. Table 19-3 provides the details on the GPIO pins.

The use of GPIO overrides is intended for development since these pads are used for other purposes in deployed products. Freescale recommends controlling the boot configuration by eFUSEs in deployed products and reserving the use of the GPIO mode for development and testing purposes only.

19.3 Device Configuration

This section describes the external inputs that control the behavior of the Boot ROM code. This includes boot device selection (NAND, NOR, MMC), boot device configuration (NAND address cycles), and so on. In general, the source for this configuration comes from eFUSEs embedded in this device. However, certain configuration parameters can be sourced from GPIO pins allowing further flexibility during the development process.

19.3.1 Boot eFUSE Descriptions

The table below is a comprehensive list of the configuration parameters that the device ROM uses.

Table 19-2. BOOT eFuse Descriptions

Fuse	Config	Definition	GPIO[1]	Shipped Value	Settings[2]
DIR_BT_DIS	OEM	Reserved FSL Test/ WDOG-1 Reset boot Mode Disable	NA	0	0 Reserved FSL Test/Watchdog Reset boot Mode is allowed 1 Reserved FSL Test/ Watchdog Reset boot Mode is not allowed

Table continues on the next page...

Table 19-2. BOOT eFuse Descriptions (continued)

Fuse	Config	Definition	GPIO[1]	Shipped Value	Settings[2]
BT_FUSE_SEL	OEM	In Boot from RCON, the BT_FUSE_SEL fuse determines whether the boot settings indicated by a Yes in the GPIO column are controlled by either GPIO pins or eFUSE settings in the IC Identification Module (IIM). In Boot From Fuses mode, the BT_FUSE_SEL determines whether device goes directly into Serial Bootloader mode, or if the boot settings are determined by eFuses.	NA	0	If BOOT_MODE[1:0] = 0b10 0 Bits of SBMR are overridden by GPIO pins. 1 Specific bits of SBMR are controlled by eFUSE settings. If BOOT_MODE[1:0] = 0b00 0 BOOT configuration eFUSEs are not yet programmed. Boot flow jumps to serial downloader. 1 BOOT configuration eFUSEs have been programmed. Regular boot flow is performed.
DIE-XCORDINATE[7:0] DIE-YCORDINATE[7:0] WAFER_NO[4:0] LOT_NO_ENC[42:40] LOT_NO_ENC[39:32] LOT_NO_ENC[31:24] LOT_NO_ENC[23:16] LOT_NO_ENC[15:8] LOT_NO_ENC[7:0]	FSL	Device Unique ID, 64-bit UID.	NA	Unique ID	Settings vary - used by HAB

3. Bank0 Word 7 Bit 16
4. Bank0 Word7 Field[31:24]

19.3.2 GPIO Boot Overrides

The table below provides a list of GPIO boot overrides. These input pins are sampled at POR, and can be used to override corresponding eFUSE values, depending on the setting of the BT_FUSE_SEL fuse. The GPIO override feature is only available when BT_FUSE_SEL is 0 (fuse is un-blown) and BOOT_MODE [1:0] = 10.

Table 19-3. GPIO Override Contact Assignments

19.3.3 Device Configuration Data

See Device Configuration Data (DCD) for more details on Device Configuration Data.

19.4 Device Initialization

This section describes the details on the device ROM and provides initialization details. This includes details on the following:

- The iROM Memory Map
- The iRAM Memory Map
- On-chip blocks that the ROM should make use of or change POR register default values
- Clock initialization
- Enabling the MMU/L2 cache when performing a secure boot (SEC_CONFIG = Closed)
- Exception handling, error logging, and interrupt handling

19.4.1 Internal ROM / RAM Memory Map

The figure below shows the internal ROM and internal RAM memory map for the device.

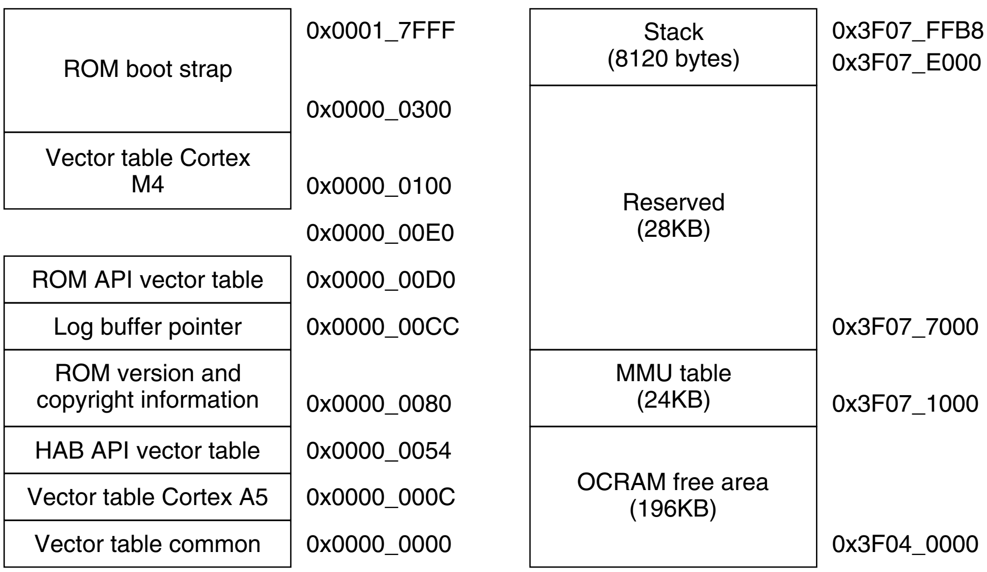

Figure 19-2. Internal ROM and RAM Memory Map

NOTE

RAM Areas will be overwritten by the BOOTROM.
Application can use this area after the control is transferred.

19.4.2 Boot Block Activation

The device Boot ROM affects a number of different hardware blocks which are activated and play a vital role in the boot flow. The ROM configures and uses the following blocks during the boot process. Note that the blocks actually used depend on the boot mode and boot device selection:

- ANADIG - Analog module. The ANADIG contains PLLs and USB PHY.
- MSCM — Miscellaneous System Configuration Module
- SRC - System Reset Controller
- CCM - Clock Control Module
- OCOTP - On-Chip OTP Controller. The OCOTP contains the eFUSEs.
- GPIO — GPIO Controller
- PIT — Programmable Interrupt Timer
- IOMUXC - I/O Multiplexer Control allows GPIO use to override eFUSE boot settings GPIO - used to choose tests in FSL Test Mode
- SPI — Serial Peripheral Interface
- FlexBus Controller - External Memory Interface. Used for NOR devices
- QuadSPI — Quad SPI controller
- I2C - Inter IC Controller
- NFC - NAND Flash controller pin interface
- USB - Used for serial download of a boot device provisioning program
- ESDHC — Enhanced Secure Digital Host Controller
- FlexCAN — CAN Controller
- UART — To Support Serial Boot
- WDOG-A5 - Watchdog Cortex-A5 Timer
- WDOG-M4 — Watchdog Cortex-M4 Timer

19.4.3 Clocks at Boot Time

Boot ROM provides facility to bypass external oscillator. This can be used by blowing OSC_BYPASS efuse. Refer to Boot eFUSE Descriptions

Boot ROM also allows customer to override the reset value of CCM_CCR[OSCNT] field by programming OSC_TUNED eFuse (Refer to Boot eFUSE Descriptions) when OSC_BYPASS eFuse is not blown. This can be helpful when the crystal startup time is more. Boot ROM performs a timed poll for CCM_CSR[FXOSC_RDY] to be asserted. The time is computed by the formula: Wait Time = 1.5*(CCM_CCR[OSCNT]/SIRC) if CCM_CSR[FXOSC_RDY] is not set within the time computed, then BOOTROM enters fail safe mode (serial download from UART).

The table below shows the various clocks and their sources used by ROM.

Table 19-4. Normal Frequency Clocks Configuration

Clock	CCM Signal	Source	Frequency(MHz)
Cortex-A5 Clock	ca5_mux_out_clk	PLL1_PFD4	264
Cortex-M4 Clock (Platform Bus Clock)	cm4_div_out_clk	PLL1_PFD4	132

Clock Name	Enabled for BOOT Device
CCPGR1_FLEXBUS	FlexBus

19.4.4 Enabling MMU and Caches

The Boot ROM includes a feature of enabling the Memory Management Unit (MMU) and caches to improve the boot speed when performing a secure boot with SEC_CONFIG = Closed (High Assurance Boot (HAB)). L1 data cache, L2 cache and MMU are enabled during image authentication.

By default L1 I-Cache is enabled.

The MMU feature is controlled by the BT_MMU_DISABLE eFUSE. By default the BT_MMU_DISABLE eFUSE is not blown meaning the ROM uses MMU, L1 Data and L2 caches of the Cortex-A5 core. The ROM establishes a page table in the MMU Page Table area of iRAM. The ROM also configures the L1 and L2 cache as write through. This improves the performance of the HAB signature verification software.

During normal boot , enabling the MMU and setting the CSF pointer in the Image Vector Table to NULL has no impact on the boot performance. When SEC_CONFIG=Open is the final configuration, it is recommended to blow the BT_MMU_DISABLE fuse. The Table below describes the relationship between BT_MMU_DISABLE and L2_CACHE_DISABLE fuse bits and its impact on BOOTROM implementation for Cortex-A5 and Cortex-M4 cores:

Table 19-6. Impact of BT_MMU_DISABLE & L2_CACHE_DISABLE on BOOTROM Implementation

Booting Core	BT_MMU_DISABLE	L2_CACHE_DISABLE	Remarks
Cortex-A5	0	0	L1-DCache, MMU & L2 Cache enabled
	0	1	L1-DCache, MMU Enabled & L2 Cache disabled
	1	X	L1-Dcache, MMU & L2 Cache Disabled
Cortex-M4	X	X	L1-DCache enabled

Note

If the Cortex-M4 is the primary core, the MMU and L2 Cache Controller are not supported.

19.4.5 WDOG_ENABLE eFUSE

WDOG_ENABLE eFUSE is used to enable Watchdog during Boot. By default this fuse will not be blown (0). Watchdog is configured to generate System Reset instead of Interrupt during boot. However this can be changed by application code after leaving the BootROM. Watchdog, once started, cannot be stopped or disabled, hence, it becomes application's responsibility to service watchdog before it expires.

If the fuse is 1, then the BootROM sets WDOG_WCR[WDE] to 1 with a timeout of 90 seconds. This gives 90 seconds to download, authenticate, and jump to application code. If this fails to happen, then a system reset will be issued. Note that the watchdog is serviced before jumping to application code, giving the user code 90 seconds to service the watchdog again.

In case of plugin download, watchdog is serviced before and after plugin is executed. This will mean that plugin code has to ensure that the watchdog is serviced every 90 seconds (to prevent watchdog trigger) during the period application code is downloaded to the internal memory. In case of Serial Download (USB & UART) and FLEXCAN boot modes, BOOTROM periodically services watchdog, allowing 90 seconds window for every transmission/reception of command and data

19.4.6 Exception Handling

The exception vectors located at the start of iROM (see Internal ROM / RAM Memory Map for vector table location) are used to map all the ARM exceptions.

During boot phase of primary core, all exception vectors other than reset vector point to Serial Downloader in iROM. In case of exceptions after low power exit, system will reboot by triggering Watchdog.

During the boot phase of secondary core, the exception vectors point to function that sets error status registers (see Persistent Bits), sends wakeup error interrupt and performs Wait-For-Interrupt instruction. Interrupt Service routine of primary core must reconfigure system and reset the secondary core.

19.4.7 Interrupt Handling during Boot

No special interrupt handling routines are required during the boot process. Interrupts are disabled during boot ROM execution and may be enabled later in application code.

19.4.8 Persistent Bits

Some modes of Boot ROM require registers that keep their values after warm reset. SRC General Purpose registers are used for this purpose. These bits are cleared only during Power On Reset. See the table below for persistent bits list and description.

Table 19-7. Persistent Bits

Bit Name	Bit Location	Description
PERSISTENT_ENTRY0[31:0]	SRC_GPR0[31:0]	Holds entry function for primary core for waking-up from low power mode.
PERSISTENT_ARG0[31:0]	SRC_GPR1[31:0]	Holds argument of entry function for primary core for waking-up from low power mode.
PERSISTENT_ENTRY1[31:0]	SRC_GPR2[31:0]	Holds entry function for secondary core.
PERSISTENT_ARG1[31:0]	SRC_GPR3[31:0]	Holds argument of entry function for secondary core.
PERSIST_SECONDARY_BOOT	SRC_ROM4[30]	This bit identifies which image must be used - primary and secondary. Used only for boot modes that support redundant boot.
PERSIST_BLOCK_REWRITE	SRC_ROM4[29]	Not used
PERSIST_WDOG_BOOT	SRC_ROM4[28]	This bit is set for enabling SBMR shadow register during Watchdog Reset Boot Mode. See Watchdog Reset Boot Mode for more details.
CPU1_ERROR_STATUS	SRC_ROM4[25]	Secondary core error status bit
PERSIST_SBMR_SHADOW	SRC_ROM3[31:0]	These bits are used as shadow SBMR registers during Watchdog Reset Boot Mode. See Watchdog Reset Boot Mode for more details.

19.5 Boot Devices (Internal Boot)

This device supports the following boot Flash devices/interfaces:

- Quad SPI Flash Memory
- NOR Flash with FlexBus, located on CS0 or CS1, 8, 16 or 32 bit multiplexed or non-multiplexed bus widths. (32bit non-multiplexed is not supported)
- Nand Flash memory (MLC or SLC NAND Devices), Pages sizes ranging from 2K – 8K supported.
- SD/MMC/eSD/eMMC4.3 via ESDHC interface, supporting high capacity cards

- EEPROM boot via SPI (Serial Flash) or I2C (via SPI and I2C blocks respectively).
- FlexCAN Boot.

The selection of Boot Device type is controlled by BOOT_CFG1[7:4] eFUSEs.

See the table below for more details:

Table 19-8. BOOT Device Selection

BOOT_CFG1[7:4]	Boot Device
0000	QSPI Serial Flash Memory
0001	NOR Flash (FlexBus Interface)
0010	Serial-ROM (SPI or I2C)
0011	FlexCAN Boot
0100	Reserved
0101	Reserved
0110	SD/eSD
0111	MMC/eMMC
1XXX	NAND Flash

19.5.1 QuadSPI Serial Flash Memory Boot

19.5.1.1 QuadSPI eFUSE Configuration

Fuse	Config	Definition	GPIO[1]	Shipped Value	Settings
BOOT_CFG1[7:4]	OEM	Boot Device Selection	Yes	0000	0000 – Boot from QuadSPI
BOOT_CFG1[1]	OEM	QuadSPI Interface selection	Yes	0	0 – QuadSPI0 selected 1 – QuadSPI1 selected

1. Setting can be overridden by GPIO settings when BT_FUSE_SEL fuse is intact. See Table 19-3 for corresponding GPIO pin.

19.5.1.2 QuadSPI Serial Flash BOOT Operation

The Boot ROM will attempt to boot from QuadSPI flash if the "BOOT_CFG1[7:4]" fuses are programmed to "0000" as shown in the QuadSPI eFUSE Configuration table. The ROM will initialize the requested the QuadSPI Interface as selected in Fuse bit BOOT_CFG1[1] in the QuadSPI eFUSE Configuration. QuadSPI interface initialization

is a two step process. The ROM expects the QuadSPI configuration parameters as explained in the QuadSPI Configuration Parameters to be present in the Serial Flash memory from the starting location of serial flash to the 318 byte offset. The ROM reads these configuration parameters using the default read command configured in the LUT of the QuadSPI interface with SCLOCK operating at 18Mhz.

In the second step, ROM configures the selected QuadSPI interface with the configuration parameters read from the serial flash and starts the boot procedure. Refer to Table 19-12 for details regarding QuadSPI configuration parameters and to the QuadSPI boot flow chart for detailed boot flow chart of QuadSPI.

Both booting an XIP and non XIP image is supported from serial flash. For XIP boot, the image has to be built for QuadSPI address space and for non XIP the image can be built to execute from DDR or SRAM.

For QUAD mode boot, the Boot ROM expects the Quad Enable bit inside the QSPI Flash to be already set before booting starts. Therefore, the QUAD enable bit must be set in the non-volatile register of the flash at the time of programming.

Note

In Case of Cortex-M4 Boot, with QSPI0, the application image entry pointer in IVT must point to QSPI0 memory region (0x2000_0000-0x2FFF_FFFF) instead of Code Alias Region (0x1000_0000-0x17ff_ffff). Application can jump to alias region for execution internally. In case of Low Power Standby Exit (for Both Cortex-A5 and Cortex-M4), Application must program STBY Exit routine in iRAM. QSPI clocks will be disabled.

19.5.1.3 IOMUX Configuration for QuadSPI

The table below shows QuadSPI IOMUX pin configuration.

Table 19-9. QuadSPI Pin Configuration

Table 19-12. QuadSPI Configuration Parameters (continued)

Name	Offset	Size in Bytes	Description
Mode of operation of serial Flash	52	1	This field describes the mode of operation of Serial flash Value / Mode: 01 – Single 02 – Dual 04 – Quad
Serial Flash Port B Selection	53	1	Port A is always available. This field informs the device ROM the availability of Port B. 0 – Port B is not used 1 – Port B is used
Dual Data Rate mode enable	54	1	This field enables the device ROM to enable DDR mode in QSPI. 0 – DDR mode is disabled 1 – DDR mode is enabled
Data Strobe Signal enable in Serial Flash	55	1	This field enables Data Strobe signal in Serial Flash which supports it. 0 – Disable DQS 1 – Enable DQS
Parallel Mode enable	56	1	This field enables the device ROM to configure the QSPI interface in parallel mode. Data will be read from serial Flash in parallel mode. Refer to QSP chapter for detail. 0 – Disable Parallel mode in QSPI 1 – Enable Parallel Mode in QSPI
CS1 on Port A	57	1	This field helps ROM to enable CS1 on port A 0 – Disable CS1 on Port A 1 – Enable CS1 on Port A
CS1 on Port B	58	1	This field helps ROM to enable CS1 on port B 0 – Disable CS1 on Port B 1 – Enable CS1 on Port B
Full Speed Phase Selection	59	1	Select the edge of the sampling clock valid for full speed commands: 0: Select sampling at non-inverted clock 1: Select sampling at inverted clock This bit is also used to shift the dqs_enable when DQS mode is selected
Full Speed Delay Selection	60	1	Select the delay w.r.t. the reference edge for the sample point valid for full speed commands: 0: One clock cycle delay 1: Two clock cycles delay This bit is also used to shift the dqs_enable when DQS mode is selected
DDR Sampling Point	61	1	Select the sampling point for incoming data when serial flash is in DDR mode. **NOTE:** Valid Values are (b000-b111)

Table continues on the next page...

Table 19-12. QuadSPI Configuration Parameters (continued)

Name	Offset	Size in Bytes	Description
LUT program sequence	62	256	256 Bytes of Look up table program sequence. ROM programs the LUT of QuadSPI with this parameter supplied. It assumes that the optimize read command sequence which will be used to read data from Serial flash and fill the AHB buffer is programmed at index 0.

The table below shows the available frequency in System Boot for booting through QuadsSPI0 with multiple configuration (SDR, DDR modes):

Table 19-13. QuadSPI SCK frequency limitation in Boot ROM

	QuadSPI0 in DDR Mode	QuadSPI0 in SDR Mode
SCK frequency options in MHz	18	18, 60, 74

19.5.1.6 QuadSPI boot flow chart

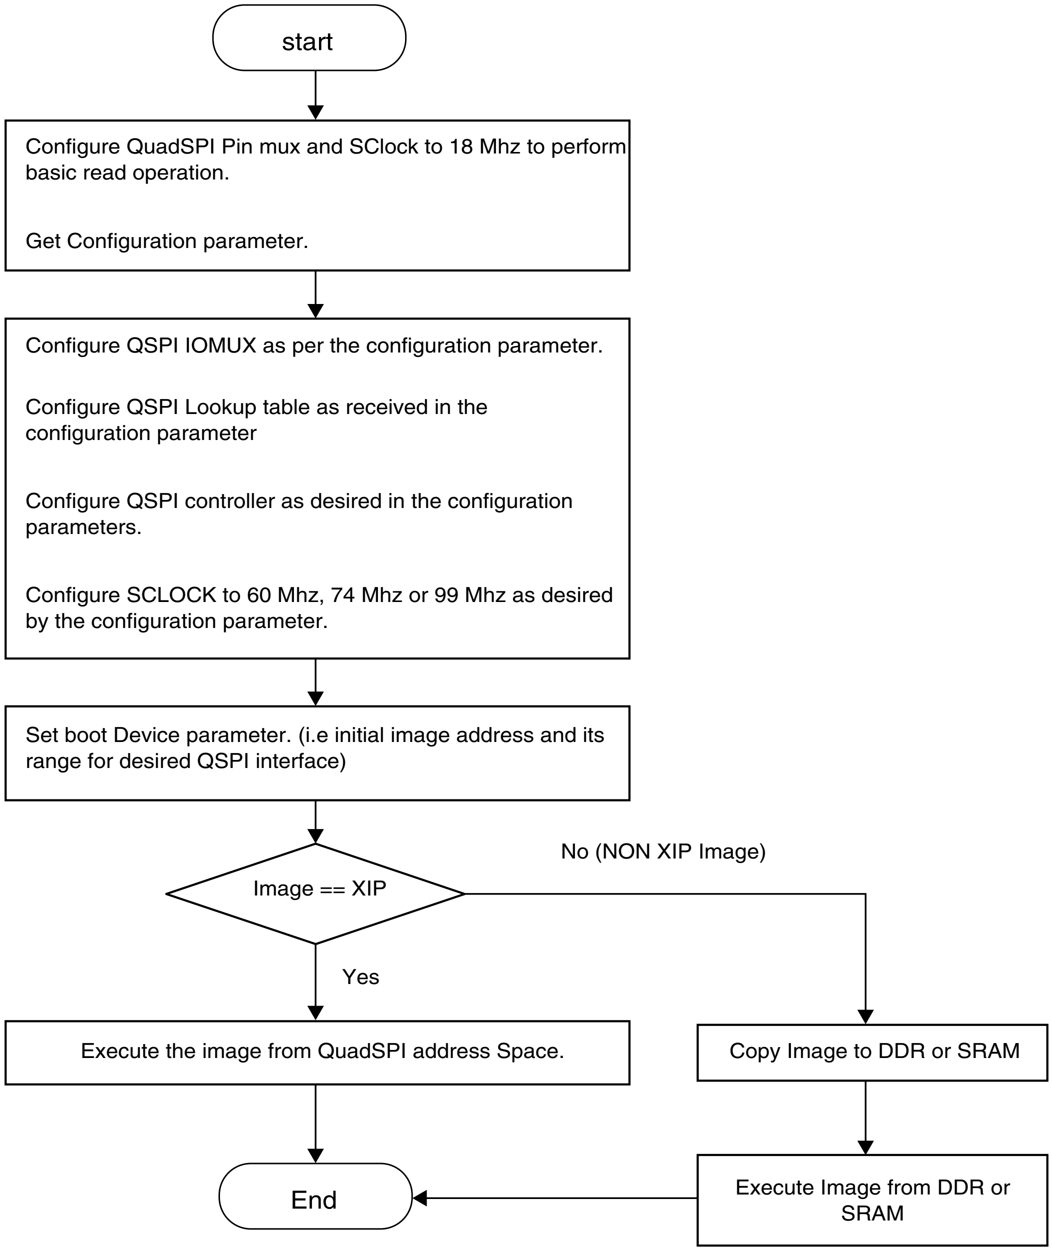

Figure 19-3. QuadSPI boot flow chart

NOTE

If flash is configured for "High performance mode (where command is generated only once)" in LUT program sequence. then external reset should be routed to flash reset to allow rebooting in case of any device reset other than Power On Reset. Also this high performance mode must be exited by application before any Low power mode entry where the device is supposed to reboot from QSPI flash on Low power mode

exit. In general, any preserved configuration in external flash will not be understood by device after reset.

19.5.2 NOR Flash Boot using FlexBus Interface

19.5.2.1 NOR Flash eFUSE Configuration

The FlexBus module works in the asynchronous mode, and supports muxed, Address/ Data, or non-muxed schemes based on fuse settings:

Table 19-14. FlexBus BOOT eFUSE Descriptions

Fuse	Config	Definition	GPIO[1]	Shipped Value	Settings
BOOT_CFG1[7:4]	OEM	Boot Device Selection	Yes	0001	0010 – Boot from FlexBus
BOOT_CFG1[3]	OEM	Chip Select	Yes	0	0 – Boot from FB_CS0 1 – Boot from FB_CS1
BOOT_CFG1[2:1]	OEM	Port Size Select	Yes	00	1X – 16 bit 01 – 8 bit 00 – 32 bit
BOOT_CFG1[0]	OEM	Multiplexed/Non-Multiplexed configuration	Yes	0	0 – Non Muxed Mode 1 – Muxed Mode
BOOT_CFG2[4:5]	OEM	Address Select	Yes	00	00 – Assert FB_CSn on the first rising clock edge after the address is asserted. 01 – Assert FB_CSn on the second rising clock edge after the address is asserted. 10 – Assert FB_CSn on the third rising clock edge after the address is asserted. 11 – Assert FB_CSn on the fourth rising clock edge after the address is asserted.
BOOT_CFG2[3]	OEM	Extended Latch Enable	Yes	0	0 – FB_TS/ALE assert for one cycle 1 – FB_TS/ALE asserted until the first positive edge after FB_CS0
BOOT_CFG2[1]	OEM	Byte Enable	Yes	0	0 – No Byte enable asserted for Read 1 – Byte enable asserted for Read
BOOT_CFG2[0]	OEM	Transfer Acknowledge	Yes	0	0 – Internal Transfer ACK 1 – External Transfer ACK

1. Setting can be overridden by GPIO settings when BT_FUSE_SEL fuse is intact. See Table 19-3 for corresponding GPIO pin.

19.5.2.2 NOR Flash Boot Operation

Booting from the NOR Flash is supported via FlexBus interface. The FlexBus interface clock is fixed to **33MHz**. The device ROM reads NOR Flash Configuration Block (see NOR Flash Configuration Block) directly from Flash. Thereafter configures FlexBus Controller parameters for optimized operation. The FlexBus IO interface clock can be increased by programming the Clock divider in FlexBus Configuration Block. Subsequently, Image Vector Table and Boot Data structures are read to determine if the image can be executed directly from FlexBus address space or should be copied to other memory. The start field of Boot Data Structure specifies the final location of the image

(see Image Vector Table and Boot Data).

NOTE

In Case of Cortex-M4 Boot, the application image entry pointer in IVT must point to the FlexBus memory region (0x3000_0000-0x3FFF_FFFF) instead of the Code Alias Region (0x1800_0000-0x1eff_ffff). Application can jump to alias region for execution internally.

In case of Low Power Standby Exit (for Both Cortex-A5 & Cortex-M4), Application must program STBY Exit routine in iRAM. FlexBus clocks will be disabled.

19.5.2.3 NOR Flash Configuration Block

NOR Flash Configuration Block is present at an offset of **0x00**, from the start of Flash memory. The block contains information for programming the FlexBus Controller.

Details of the NOR Flash Configuration Block:

Name	Start Byte	Size in Bytes	Description
Finger Print	0	4	32 bit word with a value of "0x11223344"
Flash Size	4	4	Size of NOR Flash connected
Write Protect	8	1	Flash Write Protect 0 – Disable 1 – Enable

Table continues on the next page...

Name	Start Byte	Size in Bytes	Description
Secondary Wait State Enable Flag	9	1	Flash Secondary Wait State 0 – Disable 1 – Enable
Secondary Wait State Value	10	1	Secondary Wait state Value. Used only when Secondary Wait State Enable Flag is Set.
Address Setup	11	1	Controls the Assertion of chip-select with respect to assertion of a valid address and attributes. The address and attributes are considered valid at the same time FB_ALE asserts. 00 Assert FB_CS*n* on first rising clock edge after address is asserted. (Default FB_CS*n*) 01 Assert FB_CS*n* on second rising clock edge after address is asserted. 10 Assert FB_CS*n* on third rising clock edge after address is asserted. 11 Assert FB_CS*n* on fourth rising clock edge after address is asserted. (Default FB_CS0)
Read Address Hold	12	1	This field controls the address and attribute hold time after the termination during a read cycle that hits in the chip-select address space. The hold time applies only at the end of a transfer. Therefore, during a burst transfer or a transfer to a port size smaller than the transfer size, the hold time is only added after the last bus cycle. The number of cycles the address and attributes are held after FB_CS*n* negation depends on the value of CSCR*n*[AA] as shown below.
Write Address Hold	13	1	Write address hold or deselect. This field controls the address, data, and attribute hold time after the termination of a write cycle that hits in the chip-select address space. The hold time applies only at the end of a transfer. Therefore, during a burst transfer or a transfer to a port size smaller than the transfer size, the hold time is only added after the last bus cycle. 00 Hold address and attributes one cycle after FB_CSn negates on writes. (Default FB_CSn) 01 Hold address and attributes two cycles after FB_CSn negates on writes. 10 Hold address and attributes three cycles after FB_CSn negates on writes. 11 Hold address and attributes four cycles after FB_CSn negates on writes. (Default FB_CS0)
Wait State	14	1	The number of wait states inserted after FB_CSn asserts and before an internal transfer acknowledge is generated (WS = 0 inserts zero wait states, WS = 0x3F inserts 63 wait states). If AA is reserved, FB_TA must be asserted by the external system regardless of the number of generated wait states. In that case, the external transfer acknowledge ends the cycle. An external FB_TA supersedes the generation of an internal FB_TA.
Clock Divider	15	1	The value between (1 & 8). This is used to configure the Flexbus Divider in CCM. CLK_{FBUS} = Platform Bus Clock / (Clock Divider - 1)

Table continues on the next page...

Name	Start Byte	Size in Bytes	Description
Burst-read enable.	16	1	Specifies whether burst reads are used for memory associated with each FB_CSn. 0 Data exceeding the specified port size is broken into individual, port-sized, non-burst reads. For example, a longword read from an 8-bit port is broken into four 8-bit reads. 1 Enables data burst reads larger than the specified port size, including longword reads from 8- and 16-bit ports, word reads from 8-bit ports, and line reads from 8, 16-, and 32-bit ports.
Burst-write enable	17	1	Specifies whether burst writes are used for memory associated with each FB_CSn. 0 Break data larger than the specified port size into individual, port-sized, non-burst writes. For example, a longword write to an 8-bit port takes four byte writes. 1 Enables burst write of data larger than the specified port size, including longword writes to 8 and 16-bit ports, word writes to 8-bit ports, and line writes to 8-, 16-, and 32-bit ports.
Reserved	18	14	Not Used by ROM

19.5.3 Serial ROM Boot using SPI/I2C Interface

The device supports boot from serial memory devices such as EEPROM and Serial Flash, using SPI (SPI 1, SPI 2, SPI 3, SPI 4), and I2C Controller (I2C 1, I2C 2, I2C 3, and I2C 4) interfaces.

19.5.3.1 Serial ROM eFUSE Configuration

The boot ROM code determines the type of device using the following parameters, either provided by eFUSE settings or sampled on the I/O pins, during boot (See the table below for details):

Table 19-17. Serial ROM BOOT eFUSE Descriptions

Fuse	Config	Definition	GPIO[1]	Shipped Value	Settings
BOOT_CFG1[7:4]	OEM	Boot Device Selection	Yes	0000	0010 – Boot from Serial ROM
BOOT_CFG4[5:4]	OEM	CS Select (SPI Only)	Yes	00	00 – CS#0 01 – CS#1 10 – CS#2 11 – CS#3
BOOT_CFG4[3]	OEM	SPI Addressing (SPI Only)	Yes	0	0 – 2 bytes (16 bit) 1 – 3 bytes (24 bit)
BOOT_CFG4[2:0]	OEM	Port Select	Yes	000	000 – SPI0 001 – SPI1 010 – SPI2 011 – SPI3 100 – IIC0 101 – IIC1 110 – IIC2 111 – IIC3

1. Setting can be overridden by GPIO settings when BT_FUSE_SEL fuse is intact. See Table 19-3 for corresponding GPIO pin.

The I2C-0/I2C-1/I2C-2/I2C-3 block can be used as boot device using I2C interface, for serial ROM boot. The I2C interface is configured to operate at 343.75 Kbps. The boot ROM will copy 4Kbyte of data from Serial ROM device to internal RAM. After checking the Image Vector Table header value (0xD1) from Program Image, the ROM code performs a DCD check. After successful DCD extraction, the Rom code extracts from Boot Data Structure the destination pointer and length of image to be copied to RAM device from where code execution occurs.

Note

The Initial 4K of Program Image must contain the IVT, DCD and the Boot Data structures.

19.5.3.2 SPI Boot

The Serial Peripheral Interface (SPI) interface is configured in Master mode and the EEPROM device is connected to SPI interface as slave. The boot ROM code copies 4 Kbyte data from EEPROM device to the internal RAM. If DCD verification is successful, the ROM code copies the initial 4 Kbyte data as well as the rest of image directly to application destination extracted from application image. The SPI can read data from EEPROM using 2 or 3 byte addressing and its burst length is 32 bytes.The Clock Polarity(CPOL) and Clock Phase(CPHA) bits setting of the SPI block SPIx_CTARn register are set as below during boot –

SPIx_CTARn[CPOL] = 0

SPIx_CTARn[CPHA] = 0

Note

The Serial ROM Chip Select Number is determined by BOOT_CFG4 [5:4] (Chip Select) fuse.

When using the SPI as boot device, the Vybrid supports booting from both Serial EEPROM and Serial Flash devices. The boot code determines which device is being used by reading the appropriate eFUSE/I/O values at boot (See Table 19-17 for details).

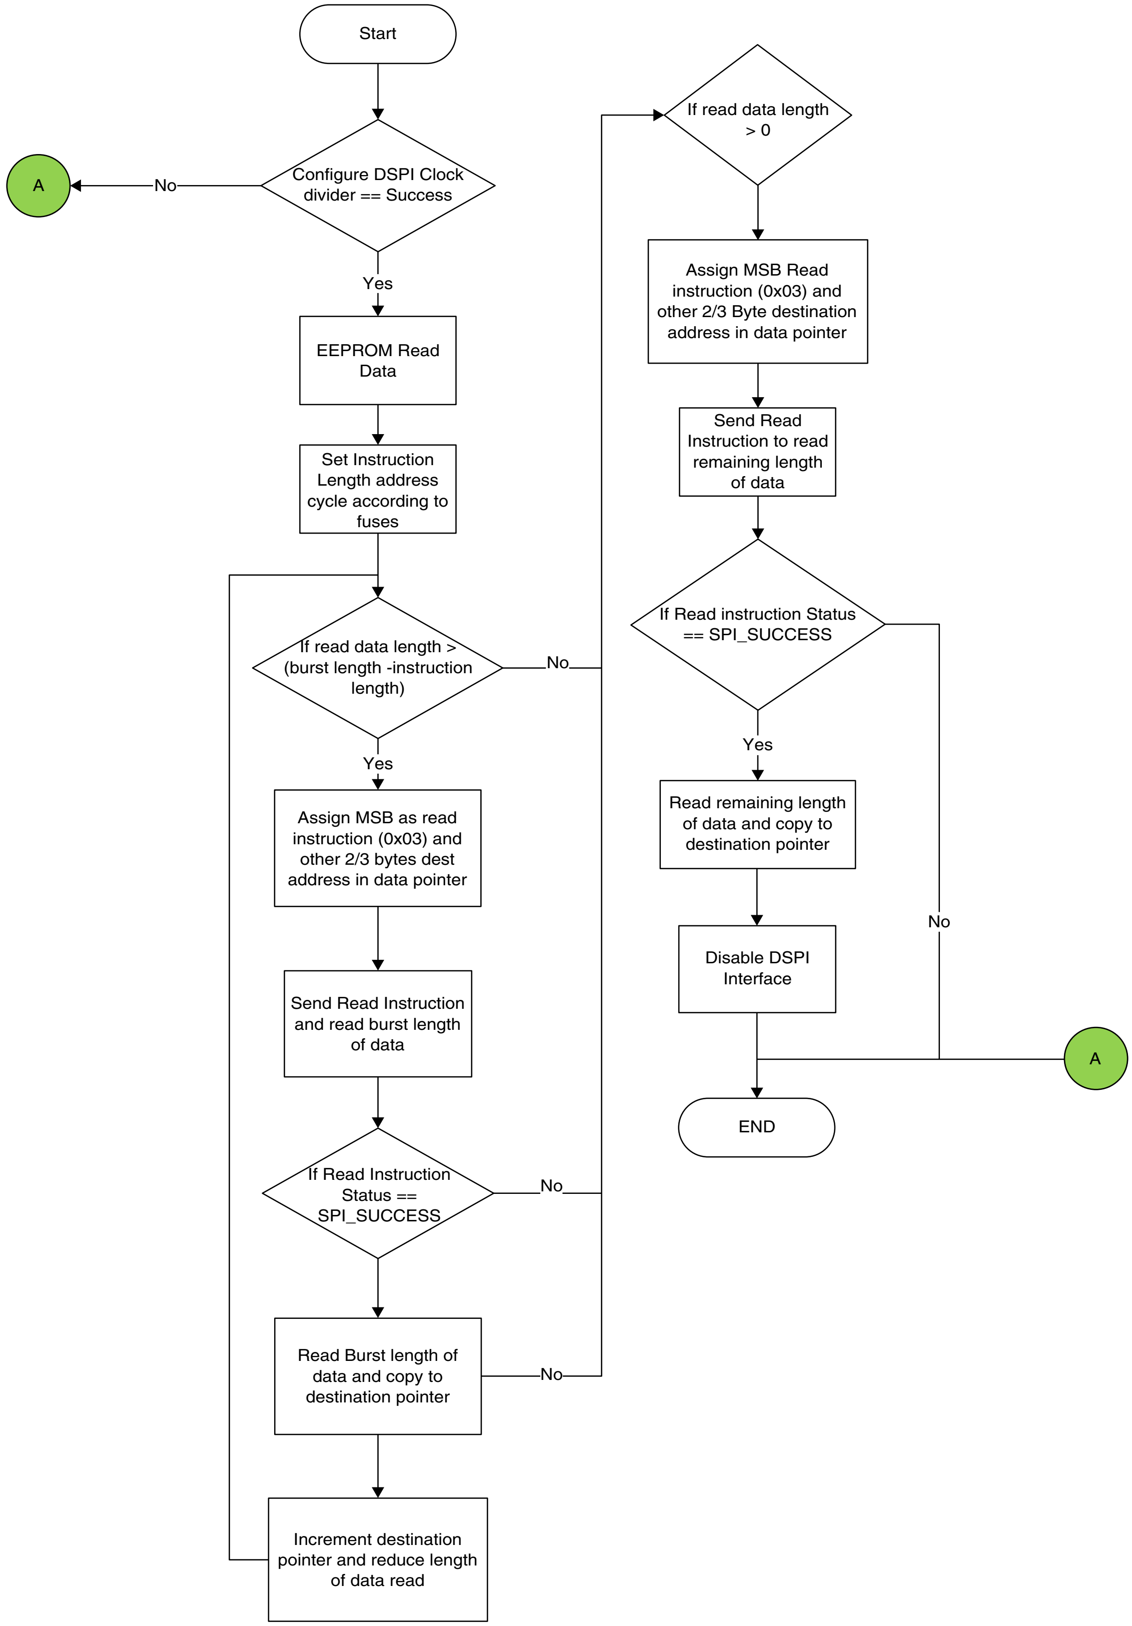

Figure 19-4. SPI Boot Flow Diagram

19.5.3.3 IOMUX Configuration for SPI

The table below shows SPI IOMUX pin configuration.

Table 19-18. SPI Pin Configuration

Signal	Pad Name			
	SPI0	SPI1	SPI2	SPI3
CS3	SAI1_RX_DATA	QSPI0_A_DATA[3]	-	-
CS2	SAI1_TX_DATA	QSPI0_A_DATA[2]	-	-
CS1	SPI0_PCS1	QSPI0_A_DATA[1]	FB_AD[31]	QSPI0_B_DATA[3]
CS0	SPI0_PCS0	QSPI0_A_DATA[0]	FB_AD[30]	QSPI0_B_DATA[2]
SIN	SPI0_SIN	QSPI0_A_DQS	FB_AD[29]	QSPI0_B_DATA[1]
SOUT	SPI0_SOUT	QSPI0_B_SCK	FB_AD[28]	QSPI0_B_DATA[0]
SCK	SPI0_SCK	QSPI0_B_CS0	FB_AD[27]	QSPI0_B_DQS

19.5.3.4 I2C Boot

The boot flow when booting from an I2C device is shown in Figure 19-5. The boot ROM code reads the fuses BOOT_CFG4[2:0] (Boot Device Selection) and BOOT_CFG1 [7:4] (Port select) to detect EEPROM device type. The ROM program copies 4K data from the EEPROM device to internal RAM. The boot ROM code next copies the initial 4Kbyte of data as well as rest of image directly to application destination extracted from application image.

The device uses the Device Select Code/Device Address in Table 19-19 to boot from an EEPROM.

Table 19-19. EEPROM via I2C Device Select Code

Bits	Device Type Identifier				Chip Enable Address[1]			R/W
	7	6	5	4	3	2	1	0
Device Select Code	1	0	1	0	0	0	0	R/W

1. These address bits, should be configured at the memory device, to match this '000' value.

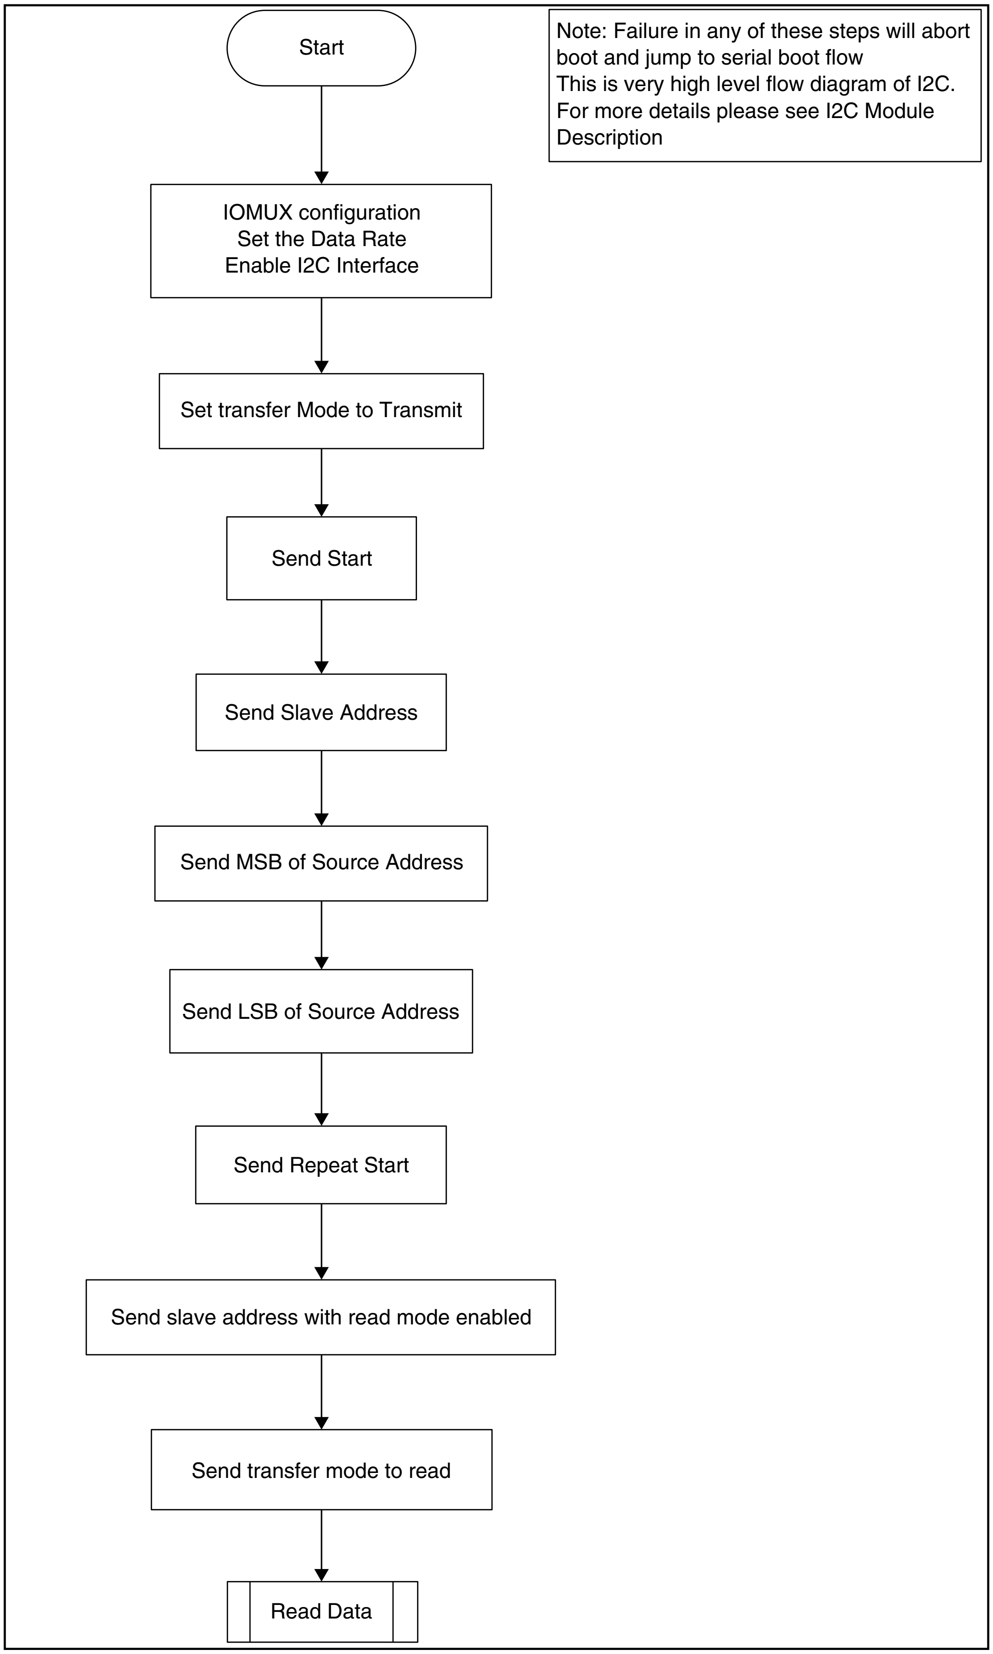

Figure 19-5. I2C Boot Flow Diagram

19.5.3.5 IOMUX Configuration for I2C

The table below shows I2C IOMUX pin configuration.

Table 19-20. I2C Pin Configuration

Signal	Pad Name			
	I2C0	I2C1	I2C2	I2C3
SCL	TRACECK	TRACED[1]	TRACED[6]	TRACED[14]
SDA	TRACED[0]	TRACED[2]	TRACED[7]	TRACED[15]

19.5.4 FlexCAN Boot

This device supports boot from CAN interfaces, either from FlexCAN0 or FlexCAN1 ports.

19.5.4.1 FlexCAN eFUSE Configuration

BOOTROM code determines the type of device using the following parameters; either provided by eFUSE settings or sampled on the I/O pins, during boot (See the table below for details):

Table 19-21. BOOT Device Selection

Fuse	Config	Definition	GPIO[1]	Shipped Value	Settings
BOOT_CFG1[7:4]	OEM	Boot Device Selection	Yes	0000	0011 – Boot From FlexCAN
BOOT_CFG1[0]	OEM	FlexCAN Port Selection	Yes	0	0 – Boot From FlexCAN0 1 – Boot From FlexCAN1

1. Setting can be overridden by GPIO settings when GPIO_FUSE_SEL fuse is intact. See Table 19-3 for corresponding GPIO pin.

19.5.4.2 FlexCAN Configuration Parameters

Either FlexCAN0 or FlexCAN1 ports can be used to download the image from an external CAN host. The FlexCAN interface is configured to operate at 1 Mbps.

Table 19-22. Bit timing parameters in FlexCAN

FlexCAN Parameter	Value (in Time Quanta)	CAN2.0 Parameter	Value (in Time Quanta)
SYNC_SEG	1	SYNC_SEG = FlexCAN SYNC_SEG	1
PROP_SEG	3	PROP_SEG = FlexCAN PROP_SEG+1	4
PSEG1	2	PHASE_SEG1 = FlexCXAN PSEG1+1	3
PSEG2	3	PHASE_SEG2 = FlexCAN PSEG2+1	4

19.5.4.3 FlexCAN Boot Operation

FlexCAN operates as a device, which is to be connected to an external CAN Host. The Host transfers the application image as per Serial Download Protocol. BOOTROM configures device ID as 0x04 and responds to Host with ID 0x14.

Before downloading the image, Host and device have to be associated. During this phase, the device waits for a pattern (0x67898967) from the host. After the pattern is received, it then responds with same pattern back to the host. This completes the ASSOCIATION Phase. BOOTROM waits for a period of 60 seconds for the ASSOCATION Phase before switching to Serial Download Mode (using UART/USB).

After Association phase is completed, the Host can download the application image using the Serial Download protocol. The Serial Download Protocol has the capability of DCD_WRITE before the image is downloaded to destination memory. Once the image is downloaded, CAN host must issue a JUMP command to the Vybrid CAN device so that BOOTROM can authenticate and the jump to the entry point of the downloaded image.

A data flow control mechanism is required between the host and device for downloading image over FlexCAN interface. A software flow control mechanism has been developed below SDP protocol layer as shown in the following figure:

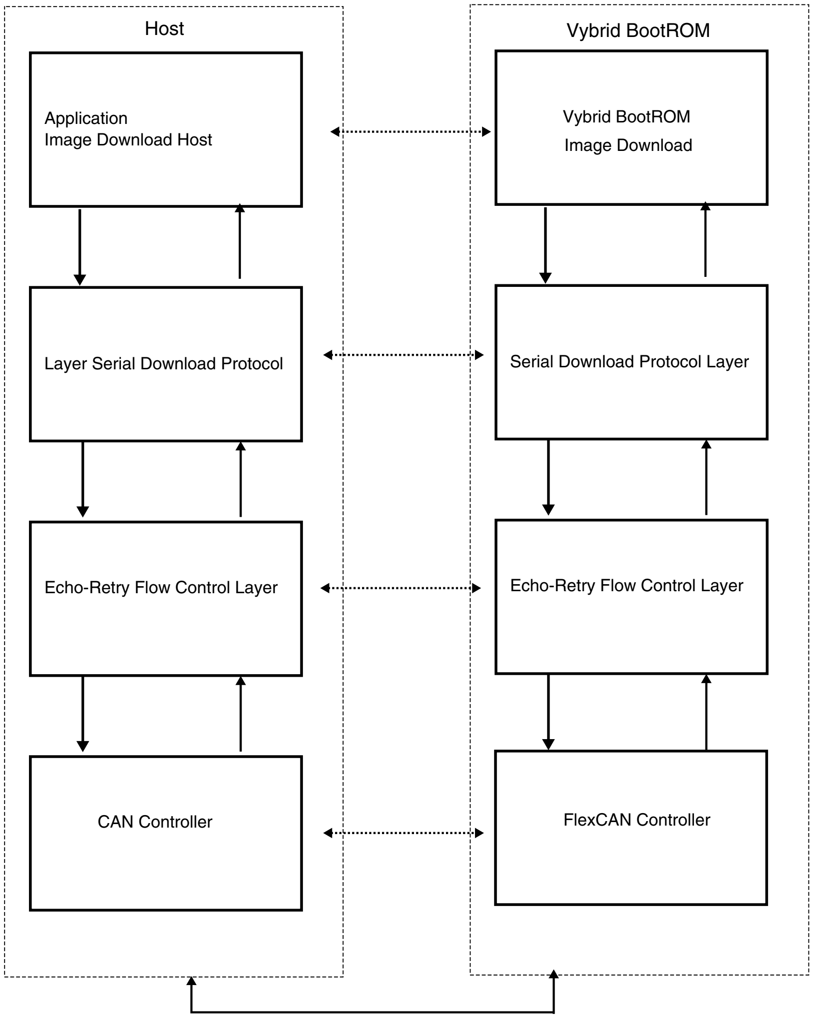

Figure 19-6. FlexCAN Boot Protocol

From Bottom up, the CAN boot architecture is similar to OSI layer architecture consisting of Physical, Data Link/flow control, Transport and Application layers only.

On top of FlexCAN controller, BOOTROM implements an echo-retry flow control mechanism in software. This mechanism has a concept of echoing back the data by the receiver which has been sent by a sender. In this architecture, a sender is an entity who has some data to send (as an originator) as per the upper layer protocol, which is SDP here. For example, SDP commands are always sent by Host, so the host will be called a sender, whereas Vybrid device will be called a receiver. Again, as the SDP responses are always sent back by Vybrid device, so the device will be a sender in this case, and host being a receiver, Echo back mechanism assures the sender doesn’t send the next data to the receiver as it has to wait to receive the echo data of the last data sent to the intended receiver, which is Vybrid device here.

Only Echo back mechanism is not enough for stable flow control, as SDP protocol has data flowing from both Host (command, data) and Devices (response, data). So in cases (especially when there is a switch between the sender and receiver functions between the host and device, e.g., sending command to receiving response or otherwise), either entity may miss a data. So a Retry mechanism is implemented to take care of this scenario. To be able to download the image properly, the host application has to implement the layered application as described above.

NOTE

ECC detection and correction operation of FlexCAN internal RAM Memory is enabled by default. Boot Code thus initializes FlexCAN internal RAM area only if FlexCAN is selected for boot operation. During boot operation, if any un -correctable Errors detected, FlexCAN port is put into Freeze mode and the boot through FlexCAN is failed (and then may jump to recovery interface or serial downloader, as the case may be).

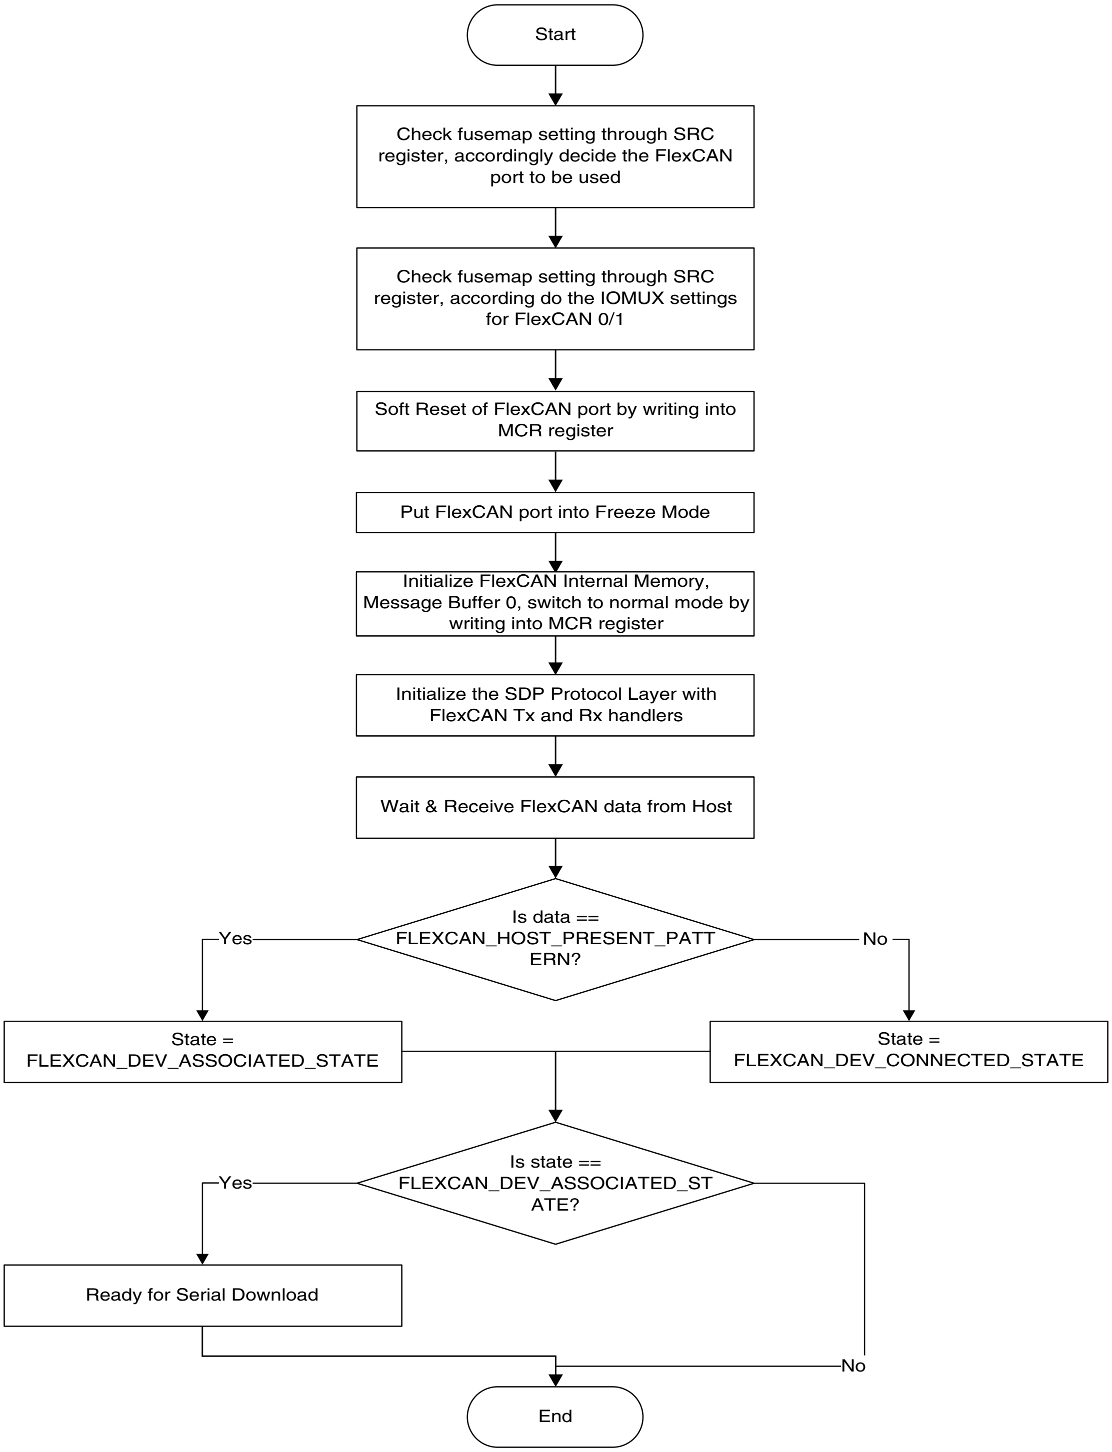

Figure 19-7. FlexCAN Flow Chart

19.5.4.4 IOMUX Configuration for FlexCAN

The table below shows FlexCAN IOMUX pin configuration.

Table 19-23. FlexCAN Pin Configuration

Signal	Pad Name	
	FlexCAN0	FlexCAN1
RX	CAN0_RX	CAN1_RX
TX	CAN0_TX	CAN1_TX

19.5.5 SD/MMC Boot

The device ROM supports booting from MMC/eMMC and SD/eSD compliant devices.

19.5.5.1 SD/MMC eFUSE Configuration

SD/MMC/eSD/eMMC boot can be performed using either ESDHC-0, ESDHC-1 ports, based on setting of the BOOT_CFG2 [3] (Port Select) fuse or its associated GPIO input value at boot. All eSDHC ports support eMMC4.3 and fast boot. See the table below for details.

Table 19-24. ESDHC BOOT eFUSE Descriptions

Fuse	Config	Definition	GPIO[1]	Shipped Value	Settings
BOOT_CFG1[7:5]	OEM	Boot Device Selection	Yes	000	011 – BOOT from eSDHC interface
BOOT_CFG1[4]	OEM	SD/MMC Selection	Yes	0	0 – SD/eSD 1 – MMC/eMMC
BOOT_CFG1[3]	OEM	Fast Boot Enable	Yes	0	0 – Fast Boot Enable 1 –Fast Boot Disable
BOOT_CFG1[1]	OEM	SD /MMC Speed	Yes	0	1 – Normal 0 – High
BOOT_CFG2[7:5]	OEM	Bus Width/SD Calibration Step	Yes	000	SD/eSD (BOOT_CFG1[5]=0) Bus Width xx0 - 1-bit xx1 - 4-bit MMC/eMMC (BOOT_CFG1[5]=1) x00 - 1-bit x01 - 4-bit x10 - 8-bit Else - reserved.

Table continues on the next page...

Table 19-24. ESDHC BOOT eFUSE Descriptions (continued)

Fuse	Config	Definition	GPIO[1]	Shipped Value	Settings
BOOT_CFG2[3]	OEM	Port Select	Yes	0	0 – ESDHC0 1 – ESDHC1
BOOT_CFG2[1]	OEM	Fast Boot Acknowledge Disable (eMMC Only)	Yes	0	0 - Boot Acknowledge Enabled. 1 - Boot Acknowledge Disabled.
BOOT_CFG2[0]	OEM	Override Pad Settings	Yes	0	0 - Use default values 1 - Use PAD_SETTINGS values

1. Setting can be overridden by GPIO settings when BT_FUSE_SEL fuse is intact. See Table 19-3 for corresponding GPIO pin.

Boot code supports following standards.

- MMCv4.3 or less
- eMMCv4.3 or less
- SDv2.0 or less
- eSDv2.10 rev-0.9, with or without FAST_BOOT.

MMC/SD/eSD/eMMC can be connected to any of ESDHC-0, 1 block and can be booted by copying 4Kbyte of data from MMC/SD/eSD/eMMC device to internal RAM. After checking the Image Vector Table header value (0xD1) from Program Image, the ROM code performs a DCD check. After successful DCD extraction, the ROM code extracts from Boot Data Structure the destination pointer and length of image to be copied to RAM device from where code execution occurs.

Note

The Initial 4Kbyte of Program Image must contain the IVT, DCD and the Boot Data structures.

Table 19-25. SD/MMC Frequencies

	SD	MMC
Identification (KHz)	400 KHz	
Normal Speed Mode (MHz)	22 MHz	18.62 MHz
High Speed Mode (MHz)	44 MHz	42.56 MHz

Note

BOOTROM code reads application image length and application destination pointer from image.

19.5.5.2 MMC and eMMC Boot

The following table provides MMC and eMMC boot details.

Table 19-26. MMC and eMMC Boot Details

Normal Boot Mode	During initialization (normal boot mode) the MMC frequency is set to 400 KHz. When the MMC card enters the identification portion of the initialization, voltage validation is performed and the ROM boot code checks high voltage settings and card capacity. The ROM boot code supports both high capacity and low capacity MMC/eMMC cards. After initialization phase is complete, the ROM boot code switches to a higher frequency (18.62 MHz in Normal boot mode or 42.56 MHz in High Speed mode). eMMC is also interfaced via eSDHC and follows the same flow as MMC. The boot partition can be selected for an MMC4.x card after the card initialization is complete. The ROM code reads the BOOT_PARTITION_ENABLE field in the Ext_CSD [179] to get the boot partition to be set. If there is no boot partition mentioned in BOOT_PARTITION_ENABLE field or the user partition has been mentioned, ROM boots from the user partition.
eMMC4.3 Device Supporting Special Boot Mode	If using an eMMC4.3 device supporting special boot mode, it can be initiated by pulling the CMD line low. If BOOT ACK is enabled, the eMMC4.3 device sends the BOOT ACK via DATA lines and ROM can read the BOOT ACK [S010E] to identify the eMMC4.3 device. If BOOT ACK is enabled ROM waits 50 ms to get the BOOT ACK and if BOOT ACK is received by ROM. If BOOT ACK is disabled ROM waits 1 second for data. If BOOT ACK or data was received then eMMC4.3 is booted in "Boot mode", otherwise eMMC4.3 boots as a normal MMC card from the selected boot partition. This boot mode can be selected by BOOT_CFG1 [3] (Fast Boot) fuse. BOOT ACK is selected by BOOT_CFG2 [1].

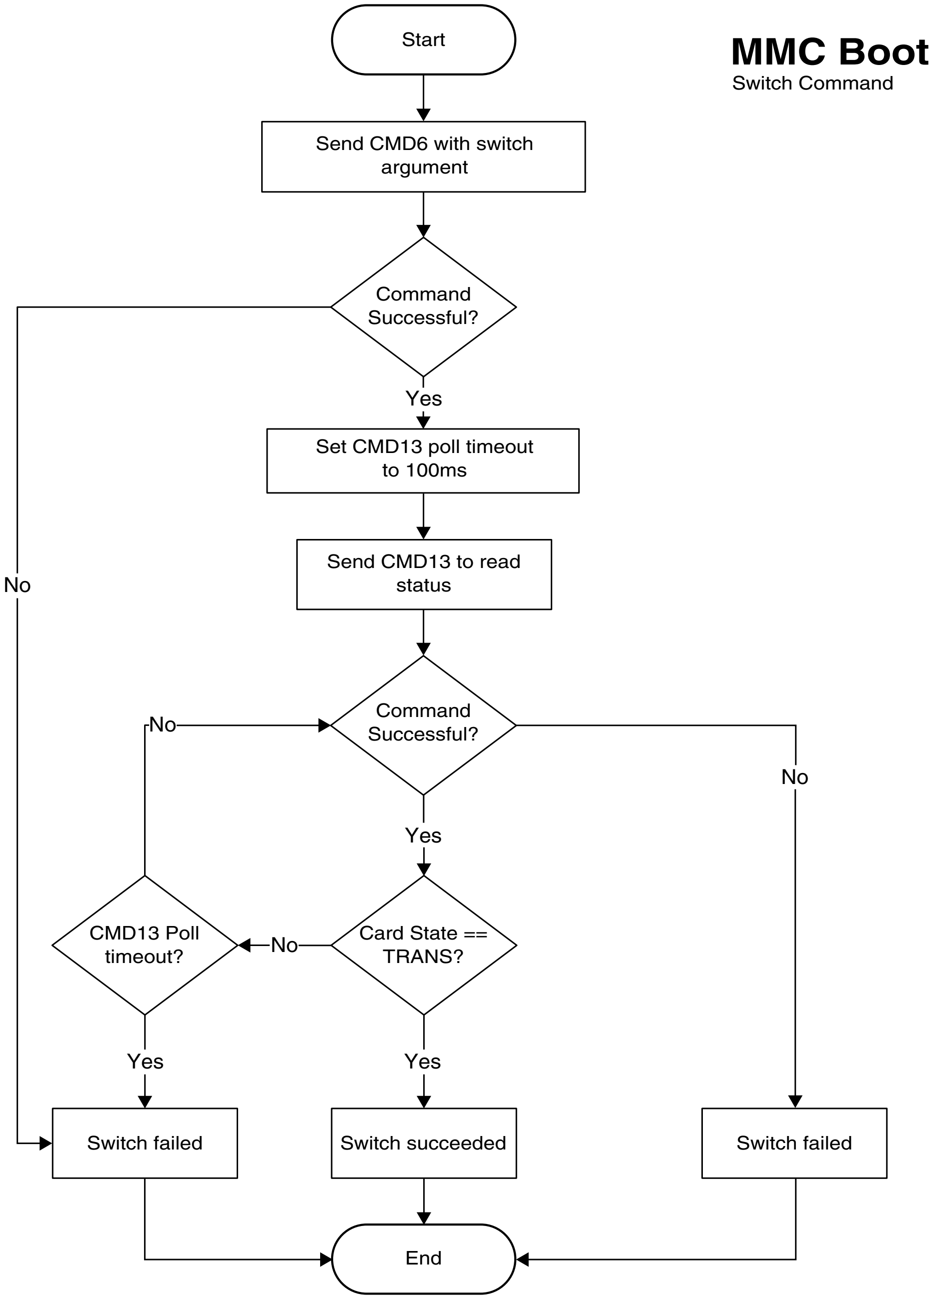

Figure 19-13. Expansion Device Boot Flow (6/7)

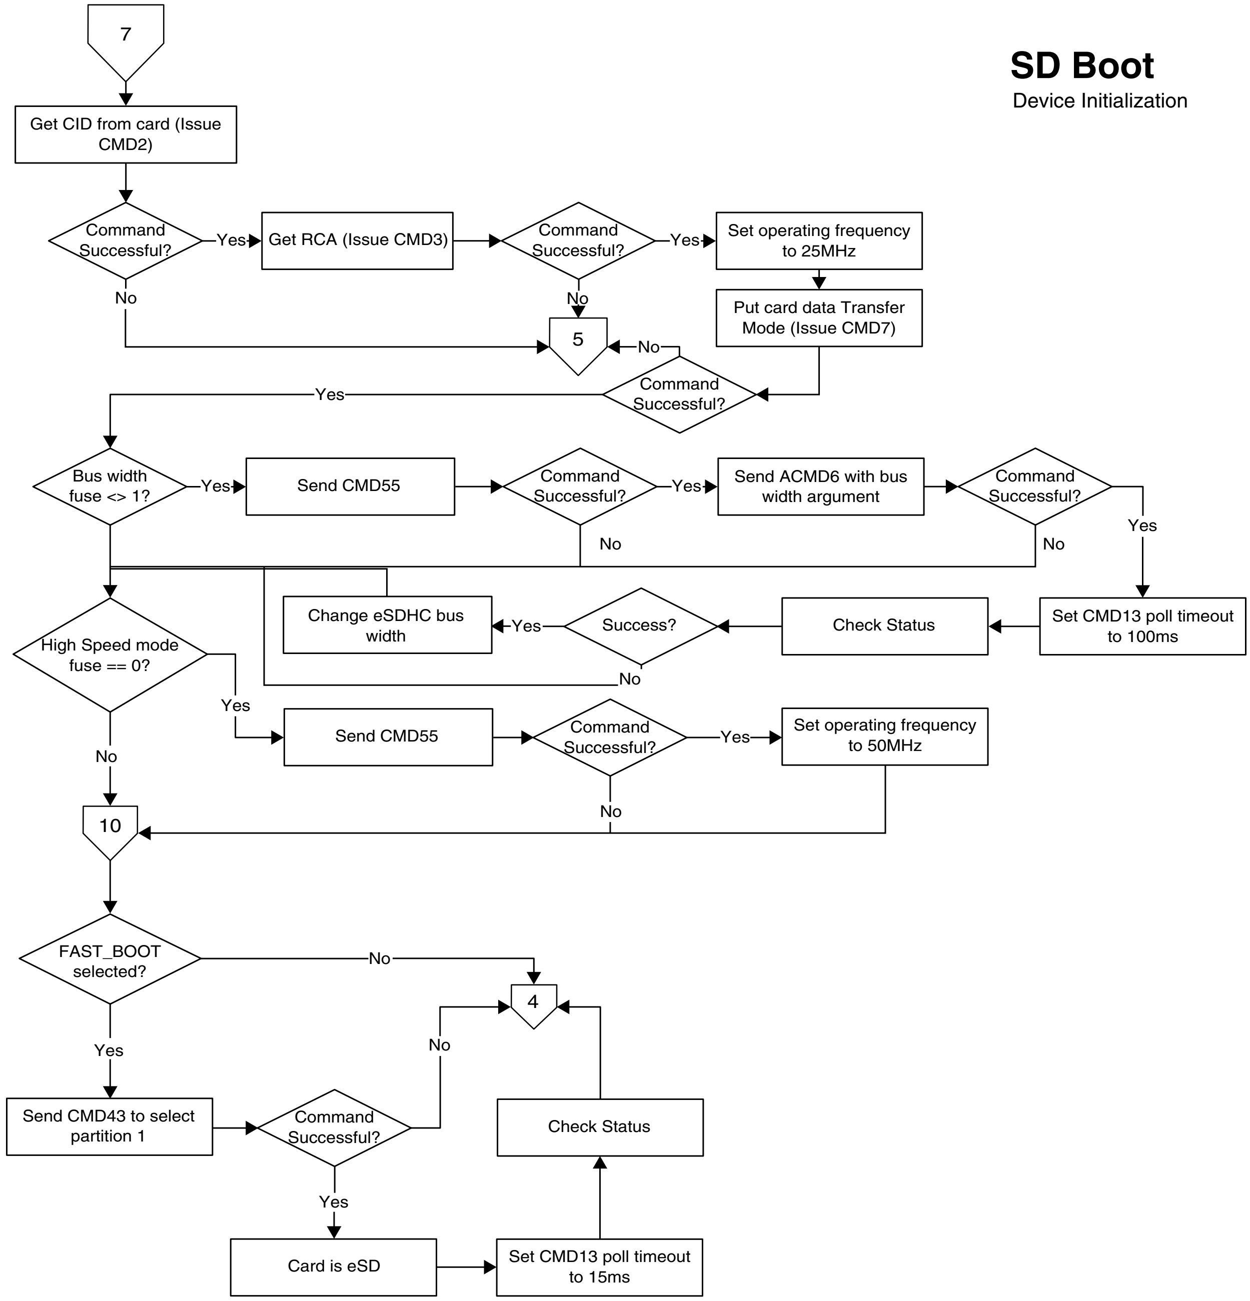

Figure 19-14. Expansion Device Boot Flow (7/7)

19.5.5.3 SD, eSD Boot

After the normal boot mode initialization begins, the SD/eSD frequency is set to 400 KHz. During the identification phase, SD/eSD card voltage validation is performed. During voltage validation, boot code first checks with high voltage settings; if that fails, it checks with low voltage settings. The capacity of the card is also checked. Boot code supports high capacity and low capacity SD/eSD cards after voltage validation card initialization is done.

During card initialization, the ROM boot code attempts to set the boot partition for all SD and eSD devices. If this fails, the boot code assumes the card is a normal SD card. If it does not fail, the boot code assumes it is an eSD card. After the initialization phase is over, boot code switches to a higher frequency (22 MHz in Normal Speed mode or 44 MHz in High Speed Mode).

The SD clock speed can be selected by BOOT_CFG1 [1].

19.5.5.4 IOMUX Configuration for SD/MMC

The table below shows ESDHC IOMUX pin configuration.

Table 19-27. ESDHC Pin Configuration

Signal	Pad Name

19.5.5.6 Redundant Boot Support for Expansion Device

The device ROM supports redundant boot for expansion device. Primary or Secondary image is selected depending on PERSIST_SECONDARY_BOOT setting (see Table 19-7).

If PERSIST_SECONDARY_BOOT is 0, the boot ROM uses address 0x0 for primary image.

If PERSIST_SECONDARY_BOOT is 1, the boot ROM will read secondary image table from address 0x200 on boot media and will use address specified in the table.

Table 19-30. Secondary Image Table Format

Reserved (chipNum)
Reserved (driveType)
tag
firstSectorNumber
Reserved (sectorCount)

Where:

- tag: used as indication of valid secondary image table. Must be 0x00112233.
- firstSectorNumber is the first 512B sector number of the secondary image.

For secondary image support, the primary image must reserve space for secondary image table. See the figure below for typical structures layout on expansion device.

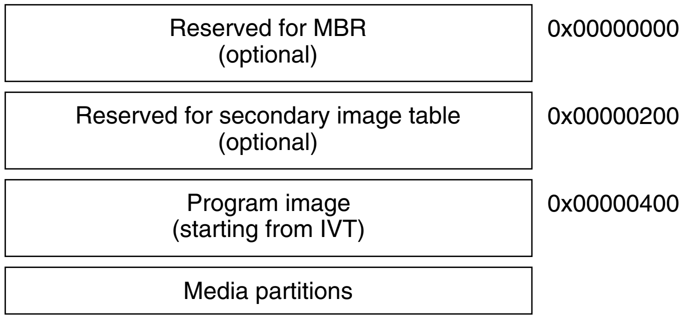

Figure 19-15. Expansion Device Structures Layout

For Closed mode, if there are failures during primary image authentication, the BOOTROM will set PERSIST_SECONDARY_BOOT bit (see Table 19-7) and perform software reset. (After software reset, secondary image will be used.)

For Unsecured chip, if invalid Image Vector Table is read, then BOOTROM will set PERSIST_SECONDARY_BOOT bit (see Table 19-7) and perform software reset. (After software reset, secondary image will be used.)

NOTE

PERSIST_SECONDARY_BOOT bit can be cleared by application after boot or will be cleared automatically during Power On Reset.

19.5.6 NAND Flash Boot using NFC Interface

A number of MLC/SLC NAND Flash devices from different vendors are supported by the boot ROM. The Error Correction and Control (ECC) sub-block is used to detect the errors.

19.5.6.1 NAND Flash eFUSE Configuration

The boot ROM determines the configuration of external the NAND flash by parameters, either provided by eFUSE, or sampled on GPIO pins, during boot. See the table below for parameters details.

Table 19-31. NAND Boot eFUSE Descriptions

Fuse	Config	Definition	GPIO[1]	Shipped Value	Settings
BOOT_CFG1[7]	OEM	Boot Device Selection	Yes	0	1 – BOOT from Nand Interface

Table continues on the next page...

Table 19-31. NAND Boot eFUSE Descriptions (continued)

Fuse	Config	Definition	GPIO[1]	Shipped Value	Settings
BOOT_CFG1[6]	OEM	Nand Interface Frequency Select	Yes	0	1 – Normal Mode 33MHz 0 – Fast Mode 40MHz
BOOT_CFG1[5]	OEM	Fast Boot Acknowledge	Yes	0	1 – Fast flash timing 0 – Slow flash timing
BOOT_CFG1[3]	OEM	Nand Chip Enable	Yes	0	0 – Use Chip Enable 0 1 – Use Chip Enable 1
BOOT_CFG1[2]	OEM	Nand Interface Data Width	Yes	0	0 –8 Bit Interface 1 – 16 Bit interface
BOOT_CFG1[1:0]	OEM	Address Cycles	Yes	00	00 – 3 Address Cycles 01 – 2 Address Cycles 1X – Reserved
BOOT_CFG2[4:3]	OEM	Boot Search Count	Yes	00	0X – 2 10 – 4 11 – 8
BOOT_CFG2[2:1]	OEM	Pages in a Block	Yes	00	00 – 128 01 – 64 10 – 32 11 – Reserved

NAND_READ_CMD_CODE1[7:0][2]	OEM	Read Command Code 1	No	0	Read Command Code 1
NAND_READ_CMD_CODE2[7:0][3]	OEM	Read Command Code 2	No	0	Read Command Code 2

1. Setting can be overridden by GPIO settings when BT_FUSE_SEL fuse is intact. See Table 19-3 for corresponding GPIO pin.
2. Bank0 Word7 Field[7:0]
3. Bank0 Word7 Field[15:8]

NOTE

Nand Flash Read Command Codes are read from fuses. If Command Code 2 is 0x00 then Command Code 0x30 is used in BOOTROM.

19.5.6.2 NAND Flash Boot Flow and BOOT Control Blocks (BCB)

There are two BCB data structures: FCB and DBBT. As part of the NAND media initialization, the ROM driver searches for a Firmware Configuration Block (FCB) that contains the page address of Discovered Bad Block Table (DBBT) Search Area and start page address of primary and secondary firmware.

The hardware ECC level to use is embedded inside FCB block. The FCB data structure is itself protected using software ECC (SEC-DED Hamming Codes). Driver reads raw 2112 bytes of first sector and runs through software ECC engine that determines whether FCB data is valid or not.

If FCB is not found or ECC fails, or the fingerprints do not match, the Block Search state machine increments page number to Search Stride number of pages to read for the next BCB until SearchCount pages have been read.

If search fails to find a valid FCB, the NAND driver responds with an error and the BOOTROM enters into serial download mode.

The FCB contains the page address of DBBT Search Area, and the page address for primary and secondary boot images. DBBT is searched in DBBT Search Area just like how FCB is searched. After the FCB is read, the DBBT is loaded, and the primary or secondary boot image is loaded using starting page address from FCB.

See the flow of FCB search in the figure below.

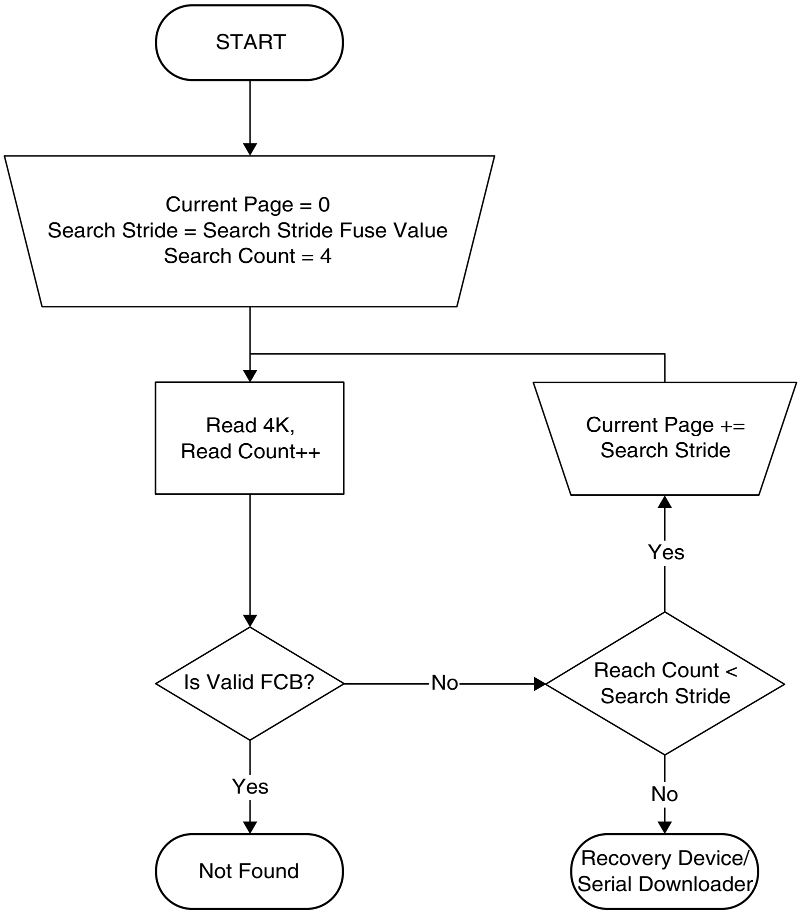

Figure 19-16. FCB Search Flow

Once FCB found the BOOTROM starts searching for Discovered Bad Blocks Table (DBBT). If DBBT Search Area is 0 in FCB, then ROM assumes that there are no bad blocks on NAND device. See the figure below for DBBT search flow.

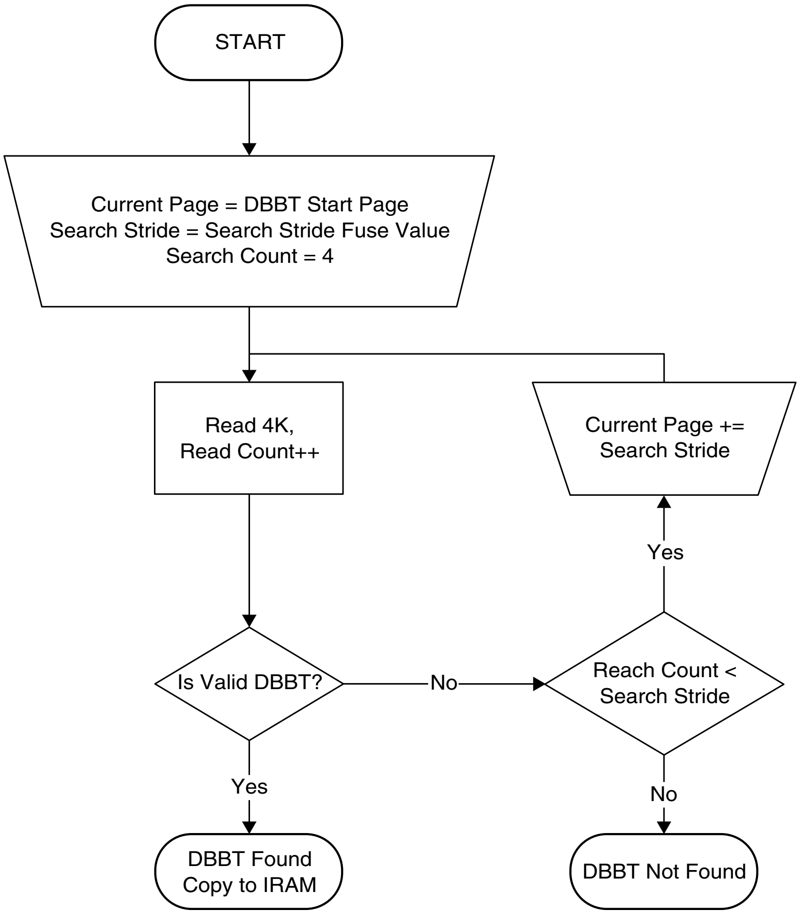

Figure 19-17. DBBT Search Flow

If during primary image read there was a page with number of errors higher than ECC can correct, the BOOTROM will turn on PERSIST_SECONDARY_BOOT bit and perform SW reset. (After SW reset secondary image will be used).

If during secondary image read there was a page with number of errors higher than ECC can correct, the BOOTROM will go to serial loader.

NOTE

PERSIST_SECONDARY_BOOT bit can be cleared by application after boot or will be cleared automatically during Power On Reset.

19.5.6.3 Firmware Configuration Block

The FCB is the first sector in the first good block. The FCB should be present at each search stride of the search area. The search area contains copies of the FCB at each stride distance, so in case the first NAND block becomes corrupted, the ROM will find its copy

in the next NAND block. The search area should span over at least two NAND blocks. The location information for DBBT search area, FW1, and FW2 are all specified in the FCB. Flash Control Block Structure is as shown in the table below.

Table 19-32. Flash Control Block Structure

Name	Start Byte	Size in Bytes	Description
Reserved	0	4	Reserved for Fingerprint #1(Checksum)
FingerPrint	4	4	32 bit word with a value of 0x46434220, in ASCII "FCB"
Version	8	4	32-bit version number; this version of FCB is 0x00000001
Reserved	12	8	Not used by ROM
DataPageSize	20	4	Number of bytes of data in a page. Typically, this is 2048 bytes for 2112 bytes page size or 4096 bytes for 4314 bytes page size
TotalPageSize	24	4	Total number of bytes in page. Typically, 2112 for 2 K page or 4224 or 4314 for 4 K page.
SectorsPerBlock	28	4	Number of pages per block. Typically 64 or 128 or depending on NAND device type.
Reserved	32	24	Not used by ROM
EccBlock0EccType	56	4	Value from 0 to 7 used to set Error Correction Type for Block of ECC page
Reserved	60	44	Not used by ROM
Firmware1_startingSector	104	4	Page number address where first copy of bootable firmware is located
Firmware2_startingSector	108	4	Page number address where second copy of bootable firmware is located
Reserved	112	8	Not used by ROM
DBBTSearchAreaStartAddress	120	4	Page address for bad block table search area
Reserved	124	8	Not used by ROM
BBMarkerPhysicalOffset	132	4	This is the offset where manufacturer leaves bad block marker on a page
Reserved	136	36	Not used by ROM
DISBBM	172	4	If 0 ROM will swap BadBlockMarkerByte with SpareArea[0] after reading a page. If the value set is 1 then ROM will not do swapping
Reserved	176	40	Not used by ROM
DISBB_Search	216	4	Disable the bad block search function when reading the firmware, only using DBBT.
Bad Block Search Limit	220	4	Number of Blocks to be searched when a Bad Block is found. By Default the value of this field is 2.

NOTE

Firmware1_startingSector, Firmware2_startingSector and DBBTSearchAreaStartAddress must point to a page in a good

Block. For performing Bad Block marker check, firmware 1 and 2 starting sectors must be block aligned.

19.5.6.4 Discovered Bad Block Table

See the table below for DBBT format.

Table 19-33. DBBT Structure

Name	Start Byte	Size in Bytes	Description
Reserved	0	4	-
FingerPrint	4	4	32-bit word with a value of 0x44424254,in ASCII "DBBT"
Version	8	4	32-bit version number; this version of DBBT is 0x00000001
Reserved	12	4	-
DBBT_NUM_OF_PAGES	16	4	Size of DBBT in pages
Reserved	20	4*PageSize -20	-
Reserved	4*PageSize	4	-
Number of Entries	4*PageSize + 4	4	Number of Bad Blocks
Bad Block Number	4*PageSize + 8	4	First Bad Block number
Bad Block Number	4*PageSize + 12	4	Second Block number
…..	….	….	….
…..	….	….	….
Last Bad Block Number	….	….	Last Bad Block number

19.5.6.5 Typical NAND Page Organization

Nand Page is divided into multiple data blocks each of size 2048 bytes. Figure below shows a typical layout of NAND page of size 4224 bytes.

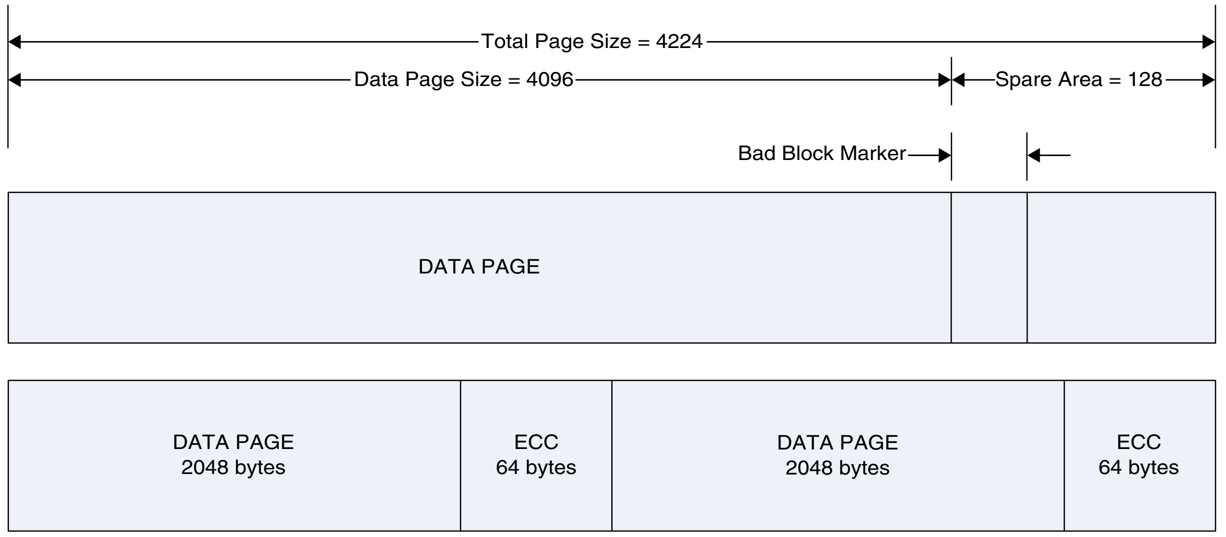

Figure 19-18. Valid Layout for 4224 bytes Sized Page

There are 2 data blocks of 2048 bytes each in a page of a 4k page sized NAND. The values of ECC should be such that above calculation should not result in a value greater than the size of a page in a 4k page NAND.

For NAND Boot, with page size restriction and data block size restricted to 2048 bytes, only a few combinations of ECC for block.

19.5.6.6 Bad Block Handling in the ROM

During firmware boot, at the block boundary, the Bad Block table is searched for a match to the next block. If no match is found, the next block can be loaded. If a match is found, the block must be skipped and the next block checked.

If Bad Block table start page is null, check the manufactory made Bad Block marker. The location of Bad Block maker is at the first 3 or last 3 pages in every block of the NAND flash. Nand manufacturers normally use one byte in the spare area of certain pages within a block to mark a block is bad or not. 0xFF means good block, otherwise means bad block.

In order to preserve the BI (bad block information), flash updater or gang programmer applications need to swap Bad Block Information (BI) data (1 byte in length) to appropriate place in DATA Area for every page before programming NAND flash.

This is calculated using the following formula.

Total Page Size -> T_{NAND} bytes

Data Page Size -> D_{NAND} bytes

Bad Block Marker Offset from start of Page -> BB_{Offset}

Total Spare Area Size -> $TSP_{NAND} = T_{NAND} - D_{NAND}$

No of Virtual Pages -> $NVP = D_{NAND} / 2048$

Spare Area Page Size per Virtual Page -> $VSP_{NAND} = TSP_{NAND} /NVP$

Virtual Page Size -> $VP_{Size} = 2048 + VSP_{NAND}$

Bad Block Marker Offset in Virtual Page ($BBOFF_{VP}$)

$BBOFF_{VP} = MOD(BB_{Offset}, VP_{Size})$

Bad Block Marker in Virtual Page count ($BBOFF_{NVP}$)

$BBOFF_{NVP} = BB_{Offset} / VP_{Size}$

ROM when loading firmware copies back 1 byte from the Virtual Page to BI offset in page data. The figure below shows how the factory bad block marker is preserved.

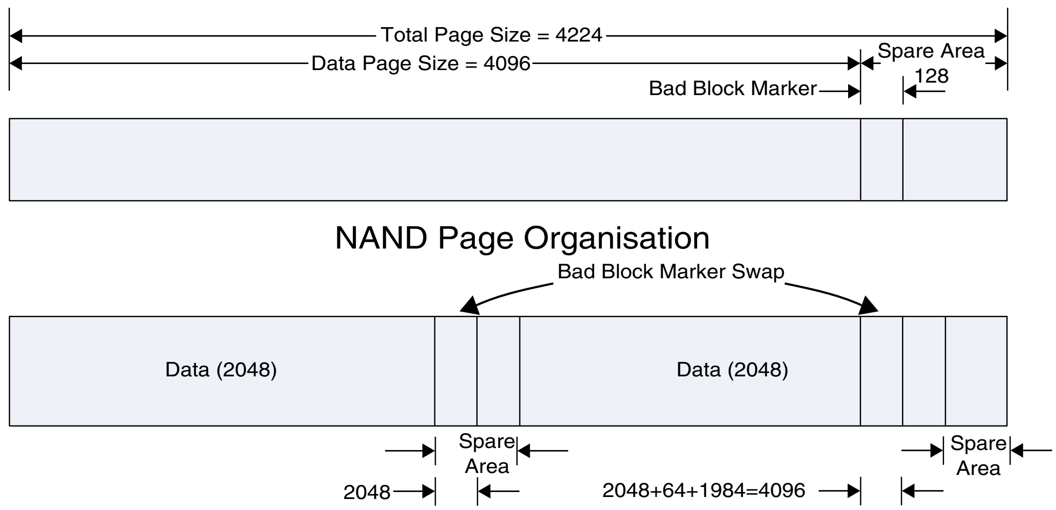

Figure 19-19. Factory Bad Block Marker Preservation

In the FCB structure, there is BBMarkerPhysicalOffset to indicate Bad Block Marker place in the page data, that manufacturer uses to mark bad block.

Table Below show typical values for different NAND Page Sizes:

Table 19-34. Bad Block Marker Position in NAND Page Layout

T_{NAND}	D_{NAND}	BB_{OFFSET}	TSP_{NAND}	NVP	VSP_{NAND}	VP_{SIZE}	$BBOFF_{VP}$	$BBOFF_{NVP}$
2112	2048	2048	64	1	64	2112	2048	0
4224	4096	4096	128	2	64	2112	1984	1
4304	4096	4096	208	2	104	2152	1944	1
8640	8192	8192	448	4	112	2160	1712	3
NOTE: Data Page Size = 2048 bytes								

19.5.6.7 Setup DMA for DDR Transfers

In DMA descriptors NAND Flash Controller is configured to read page data at double data rate, the word length is set to 16 and transfer count to half of page size.

19.5.6.8 IOMUX Configuration for NFC

The table below shows the Nand Flash Controller IOMUX pin configuration.

Table 19-35. NAND IOMUX Pin Configuration

19.6 Program Image

This section describes the data structures that are required to be included in a user's Program Image. A Program Image consists of:

- Image Vector Table- A list of pointers located at a fixed address that the ROM examines to determine where other components of the Program Image are located.
- Boot Data- A table indicating the Program Image Location, Program Image size in bytes and plugin flag.
- Device Configuration Data- IC configuration data.
- Data used by HAB- CSF command data, signatures and certificates
- User code and data

19.6.1 Image Vector Table and Boot Data

The Image Vector Table (IVT) is the data structure that the ROM reads from the boot device supplying the program image containing the required data components to perform a successful boot. The IVT includes the program image entry point, a pointer to Device Configuration Data (DCD) and other pointers used by the ROM during the boot process. The ROM locates the IVT at a fixed address that is determined by the boot device connected to Vybrid. The IVT offset from the base address and initial load region size for each boot device type is defined in the table below. The location of the IVT is the only fixed requirement by the ROM. The remainder or the image memory map is flexible and is determined by the contents of the IVT.

Table 19-37. Image Vector Table Offset and Initial Load Region Size

Boot Device Type	Image Vector Table Offset	Initial Load Region Size
NOR	4 Kbyte = 0x1000 bytes	Entire Image Size
NAND	1 Kbyte = 0x400 bytes	4 Kbyte
SD/MMC/eSD/eMMC	1 Kbyte = 0x400 bytes	4 Kbyte
I2C/SPI EEPROM	1 Kbyte = 0x400 bytes	4 Kbyte
Quad SPI	1 Kbyte = 0x400 bytes	Entire Image Size

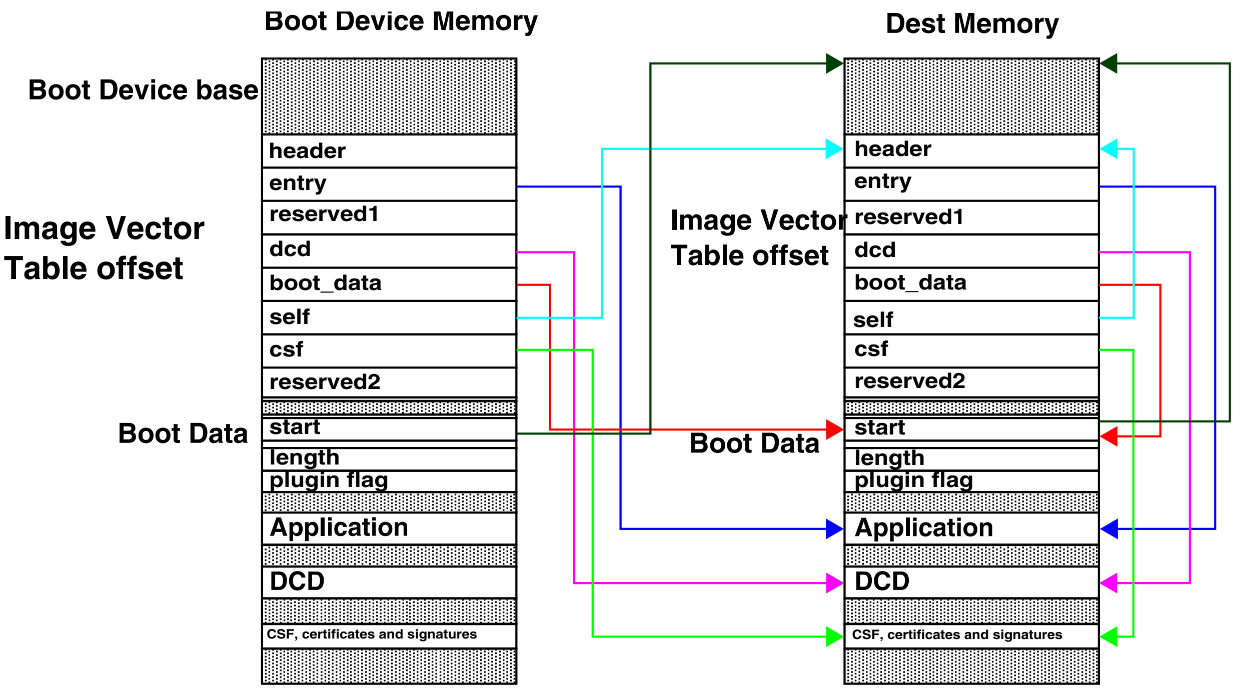

Figure 19-20. Image Vector Table

19.6.1.1 Image Vector Table Structure

The IVT has the following format where each entry is a 32 bit word:

Table 19-38. IVT Format

Header (See table 30 below)
entry: Absolute address of the first instruction to execute from the image
reserved1: Reserved and should be zero
dcd: Absolute address of the image DCD. The DCD is optional so this field may be set to NULL if no DCD is required. See Device Configuration Data (DCD) for further details on DCD.
boot data: Absolute address of the Boot Data
self: Absolute address of the IVT. Used internally by the ROM

Table continues on the next page...

Table 19-38. IVT Format (continued)

csf: Absolute address of Command Sequence File (CSF) used by the HAB library. See High Assurance Boot (HAB) for details on secure boot using HAB. This field must be set to NULL when not performing a secure boot
reserved2: Reserved and should be zero

The IVT header has the following format:

Table 19-39. IVT Header Format

Tag	Length	Version

Where:

```
Tag: A single byte field set to 0xD1
Length: a two byte field in big endian format containing the overall length of the IVT, in
bytes, including the header. (The length is fixed and must have a value of 32 bytes)
Version: A single byte field set to 0x41
```

19.6.1.2 Boot Data Structure

The Boot Data must follow the format defined in the table below; each entry is a 32-bit word.

Table 19-40. Device BOOT Data Format

start	Absolute Address of Image
length	Size of Program Image
plugin	Plug-in Flag

19.6.2 Device Configuration Data (DCD)

Upon reset, the device uses the default register values for all peripherals in the system. However, these settings typically are not ideal for achieving optimal system performance and there are even some peripherals that must be configured before they can be used. The DCD is configuration information contained in a Program Image, external to the ROM that the ROM interprets to configure various peripherals on this device. Some components such as SDRAM require some sequence of register programming as part of configuration before it is ready to be used. The DCD feature can be used to program DDRMC registers to the optimal settings.

The ROM determines the location of the DCD table based on information located in the Image Vector Table (IVT). See Image Vector Table and Boot Data for more details. The DCD table shown below is a big endian byte array of the allowable DCD commands. The maximum size of the DCD limited to 3028 bytes.

Table 19-41. DCD Data Format

Header
[CMD]
[CMD]
[CMD]
….

The DCD header is 4 bytes with the following format:

Table 19-42. DCD Header

Tag	Length	Version

Where:

```
Tag: A single byte field set to 0xD2
Length: a two byte field in big endian format containing the overall length of the DCD, in
bytes, including the header.
Version: A single byte field set to 0x40
```

19.6.2.1 Write Data Command

The Write Data Command is used to write a list of given 1, 2 or 4-byte values or bitmasks to a corresponding list of target addresses. The format of Write Data Command, again a big endian byte array, is shown in the table below.

Table 19-43. Write Data Command Format

Tag	Length	Parameter
Address		
Value/Mask		
[Address]		
[Value/Mask]		
….		
[Address]		
[Value/Mask]		

Where:

```
Tag: A single byte field set to 0xCC
Length: A two byte field in big endian format containing the length of the Write Data
Command, in bytes, including the header
Address: target address to which data should be written
Value/Mask: data value or bitmask to be written to preceding address
```

The Parameter field is a single byte divided into bitfields as follows:

Table 19-44. Write Data Command Parameter field

7	6	5	4	3	2	1	0
flags					bytes		

Where:

```
bytes: width of target locations in bytes. Either 1, 2 or 4
flags: control flags for command behavior.
Data Mask = bit 3: if set, only specific bits may be overwritten at target address
(otherwise all bits may be overwritten
Data Set = bit 4: if set, bits at the target address overwritten with this flag
(otherwise it is ignored)
```

One or more target address and value/bitmask pairs can be specified. The same bytes and flags parameters apply to all locations in the command.

When successful, this command writes to each target address in accordance with the flags as follows:

Table 19-45. Interpretation of Write Data Command Flags

"Mask"	"Set"	Action	Interpretation
0	0	*address = val_msk	Write Value
0	1	*address = val_msk	Write Value
1	0	*address &= ~val_msk	Clear bitmask
1	1	*address |= val_msk	Set bitmask

Note

If any of the target addresses does not have the same alignment as the data width indicated in the parameter field, none of the values are written.

If any of the values is larger or any of the bitmask is wider than permitted by the data width indicated in the parameter field, none of the values are written.

If any of the target addresses do not lie within an allowed region, none of the values are written. The list of blocks and target addresses allowed for this device are given below.

Table 19-46. Valid DCD Memory Address Ranges

Memory Region	Address Range	Cortex-A5	Cortex-M4
SDRAM0	0x8000_0000 - 0xDFFF_FFFF	YES	YES
TCML	0x1F80_0000 - 0x1FFF_FFFF	YES	YES
QSPI0	0x2000_0000 - 0x2FFF_FFFF	YES	YES
FlexBUS	0x3000_0000 - 0x3EFF_FFFF	YES	YES
OCRAM - Sys RAM	0x3F00_0000 - 0x3F3F_FFFF	YES	YES
OCRAM - gfx RAM	0x3F40_0000 - 0x3F7F_FFFF	YES	YES
TCMU	0x3F80_0000 - 0x3FFF_FFFF	YES	YES
QSPI1	0x5000_0000 - 0x5FFF_FFFF	YES	YES
SDRAM1	0xE000_0000 - 0xFFFF_FFFF	YES	NO
Cortex-M4 Code Alias Region	0x0080_0000 - 0x1F7F_FFFF	NO	YES

Table 19-47. Valid DCD Peripheral Address Ranges

Peripheral	Address Range	Cortex-A5	Cortex-M4
DDRMC	0x400A_E000 - 0x400A_EFFF	YES	YES
IOMUX	0x4004_8000 - 0x4004_8FFF	YES	YES
FlexBUS Controller	0x4001_E000 - 0x4001_EFFF	YES	YES
Clock Control Module	0x4006_B000 - 0x4006_BFFF	YES	YES
ANADIG	0x4005_0000 - 0x4005_0FFF	YES	YES

19.6.2.2 Check Data Command

The Check Data Command is used to test for a given 1, 2 or 4-byte bitmasks from a source address. The Check Data Command is a big endian byte array with format shown in the table below.

Table 19-48. Check Data Command Format

<table>
<tr><td>Tag</td><td>Length</td><td>Parameter</td></tr>
<tr><td colspan="3">Address</td></tr>
<tr><td colspan="3">Mask</td></tr>
<tr><td colspan="3">[Count]</td></tr>
</table>

Where:

```
Tag: A single byte field se to 0xCF
Length: A two byte field in big endian format containing the length of the Check Data
Command, in bytes, including the header
Address: source address to test
Mask: bit mask to test
Count: optional poll count. If count is not specified this command will poll indefinitely
until the exit condition is met. If count = 0, this command behaves as for NOP.
```

The Parameter field is a single byte divided into bitfields as follows:

Table 19-49. Check Data Command Parameter field

7	6	5	4	3	2	1	0
flags				bytes			

Where:

```
bytes: width of target locations in bytes. Either 1, 2 or 4
flags: control flags for command behavior.
Data Mask = bit 3: if set, only specific bits may be overwritten at target address
(otherwise all bits may be overwritten)
Data Set = bit 4: if set, bits at the target address overwritten with this flag
(otherwise it is ignored)
```

This command polls the source address until either the exit condition is satisfied, or the poll count is reached. The exit condition is determined by the flags as follows:

Table 19-50. Interpretation of Check Data Command Flags

"Mask"	"Set"	Action	Interpretation
0	0	(*address & mask) == 0	All bits clear
0	1	(*address & mask) == mask	All bits set
1	0	(*address & mask) != mask	Any bit clear
1	1	(*address & mask) != 0	Any bit set

Note

If the source address does not have the same alignment as the data width indicated in the parameter field, the value is not read.

If the bitmask is wider than permitted by the data width indicated in the parameter field, the value is not read.

19.6.2.3 NOP Command

This command has no effect. The format of NOP Command is a little endian four byte array as shown in table below.

Table 19-51. NOP Command Format

Tag	Length	Undefined

Where:

```
Tag: A single byte field se to 0xC0
Length: A two byte field containing the length of the NOP Command in bytes. Fixed to a value
of 4.
Undefined: This byte is ignored and can be set to any value.
```

19.7 Plugin Image

The device ROM supports a limited number of boot devices. To boot from other devices (for example, Ethernet), a supported boot device must be used (typically serial ROM) that includes firmware for the desired boot device.

The Boot ROM will detect the image type by using the plugin flag in the Boot Data Structure. If the plugin flag is 1, then the ROM will use the image as a plugin function. The function must initialize the boot device and copy the program image to the final location. At the end, the plugin function must return with the parameters of the program image.

The boot ROM will authenticate the plugin image prior to running the plugin function and then will authenticate the program image.

The plugin function must follow the API described below:

```
typedef unsigned char (*) plugin_download_f(void **start, size_t *bytes, UINT32 *ivt_offset)
```

ARGUMENTS PASSED:

- start - Image load address on exit.

- bytes - Image size on exit.
- ivt_offset - Offset in bytes of the IVT from the image start address on exit.

RETURN VALUE:

- 1 - on success
- 0 - on failure

19.8 Serial Downloader (BOOT_MODE [1:0] = 0b01)

The Serial Downloader provides a means to download a Program Image to the device over the USB/UART connection. In this mode, the ROM programs either WDOG-A5 or WDOG-M4 for a 32-second time-out if WDOG_ENABLE eFUSE is 1, and then continuously polls for USB connection and UART activity. If no activity is found on USB or UART and the watchdog timer expires, then the ARM core is reset.

Note

The downloaded application image must continue to service the watchdog timer to avoid an undesired reset from occurring.

The USB/UART boot flow is shown in the figure below.

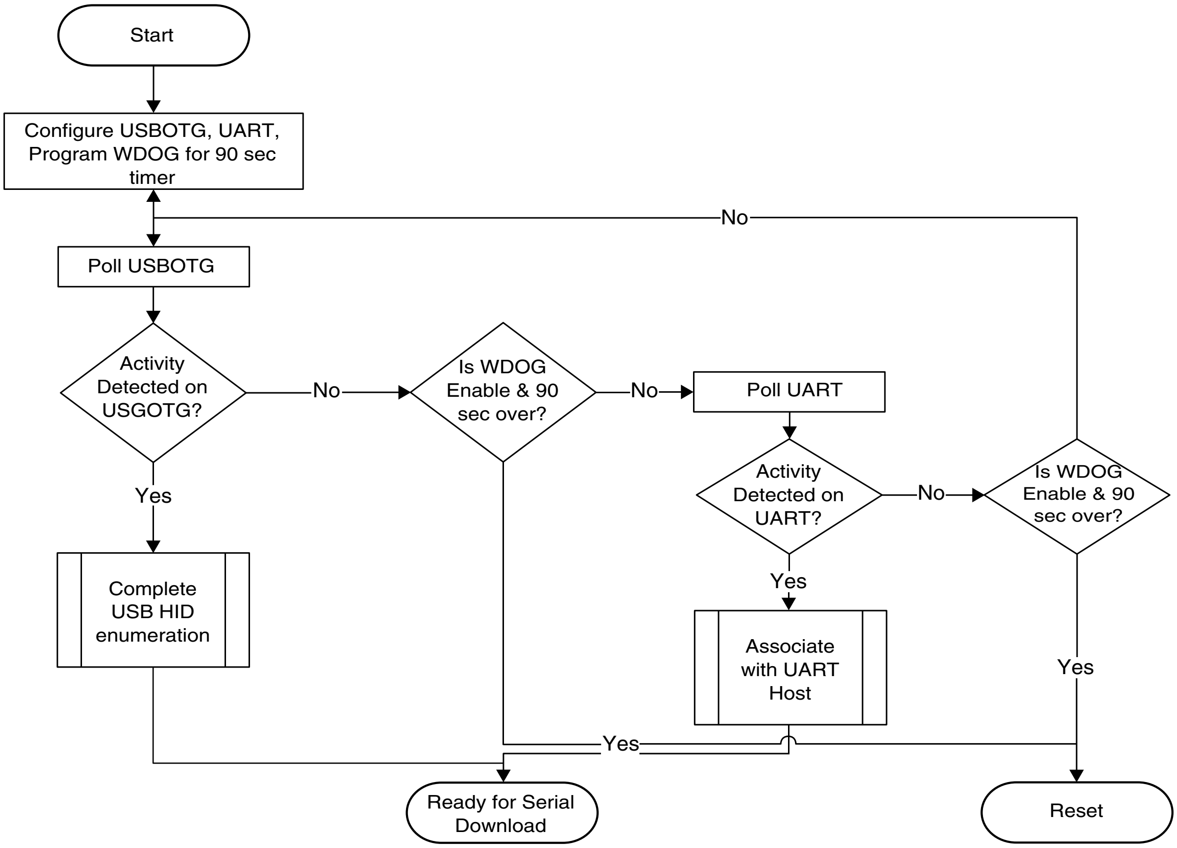

Figure 19-21. USB/UART Boot Flow

19.8.1 USB Boot Flow

USB support in this device is composed of the USB OTG core controller, compliant with the USB 2.0 specification and the USBPHY (HS USB transceiver). The device ROM supports the USB0 port for boot purposes. The other USB port on the device is not supported for boot purposes.

NOTE

Only USB0 is supported as a boot device. USB1 cannot be used.

The device USB Driver is implemented as a USB HID class. A collection of 4 HID reports are used to implement SDP protocol for data transfers:

- Report 1 transfer over Control OUT endpoint, 16-byte SDP command from host to device. Total bytes are 17 with first byte reserved for Report ID set to 1.

- Report 2 transfer over control OUT endpoint from host to device data associated with report 1 SDP command. Max report size is 1025 bytes with first byte reserved for Report ID set to 2.
- Report 3 transfer over interrupt endpoint from device to host to send HAB security state. Max size of this report is 5 bytes with first byte reserved for Report ID set to 3.
- Device sends 0x12343412 in production mode and 0x56787856 in engineering mode in the remaining 4 bytes of this report.
- Report 4 transfer over interrupt endpoint from device to host to send data in response to SDP command in report 1. Max size of this report is 65 with first byte reserved for Report ID set to 4.

19.8.1.1 USB Configuration Details

The USB OTG function device driver supports a high speed (HS for UTMI) non-stream mode with a maximal packet size of 512 B and a low-level USB OTG function.

The VID/PID and strings for USB device driver are listed in the table below.

Table 19-52. VID/PID and Strings for USB Device Driver

Descriptor	Value
VID	0x15A2 (Freescale Vendor ID)
PID[1]	0x006A
String Descriptor1 (manufacturer)	Freescale Semiconductor Inc.
String Descriptor2 (product)	
String Descriptor4	Freescale Flash
String Descriptor5	Freescale Flash

1. Allocation based on BPN (Before Part Number)

19.8.1.2 IOMUX Configuration for USB

The interface signals of the UTMI PHY are not configured in the IOMUX. The UTMI PHY interface uses dedicated contacts on the IC. See the device data sheet for details.

19.8.2 UART Boot Flow

UART support in the device is composed of the UART controller(called as Host). The device ROM supports UART0, UART1, UART2 or UART3 ports for serial download.

Initially, the selected UART port for booting waits for a data pattern (0x23454523) from the UART host. After receiving this pattern, the device sends the same pattern back to the host. This phase of of pattern exchange is called Association phase.

Once the association phase is over, the host and device UART device implements SDP protocol of data transfers:

- 16 bytes SDP Commands are sent by the UART host
- Optionally more data bytes are sent by the UART host to the device UART device
- The device UART port sends 4 bytes of HAB security state, which is 0x12343412 in production mode and 0x56787856 in engineering mode.

If required, the device UART device sends data to UART host in response to the certain SDP commands.

19.8.2.1 UART eFUSE Configuration

The boot ROM determines the configuration of UART, either provided by eFUSE, or sampled on GPIO pins, during boot. See the table below for parameters details.

Table 19-53. UART eFUSE Descriptions

Fuse	Config	Definition	GPIO[1]	Shipped Value	Settings
BOOT_CFG3[5:4]	OEM	UART Boot Device Selection	Yes	00	00 – UART0 01 – UART1 10 – UART2 11 – UART3

1. Setting can be overridden by GPIO settings when BT_FUSE_SEL fuse is intact. See Table 19-3 for corresponding GPIO pin.

19.8.2.2 IOMUX Configuration for UART

The table below shows the UART IOMUX pin configuration.

Table 19-54. UART IOMUX Pin Configuration

Signal	Pad Name			
	UART0	UART1	UART2	UART3
TX	SCI0_TX	SAI0_TX_BCLK	QSPI0_A_SCK	TRACED[14]
RX	SCI0_RX	SAI0_RX_BCLK	QSPI0_A_CS0	TRACED[15]
RTS	SCI0_RTS	SAI0_RX_DATA	QSPI0_A_DATA[3]	SAI0_TX_BCLK
CTS	SCI0_CTS	SAI0_TX_DATA	QSPI0_A_DATA[2]	SAI0_RX_BCLK

19.8.3 Serial Download protocol

The 16 byte SDP command from host to device is sent using HID report 1. The table below describes 16 byte SDP command data structure:

Table 19-55. 16 Byte SDP Command Structure

BYTE Offset	Size	Name	Description
0	2	COMMAND TYPE	Following commands are supported for the device ROM: • 0x0101 READ_REGISTER • 0x0202 WRITE_REGISTER • 0x0404 WRITE_FILE • 0x0505 ERROR_STATUS • 0x0A0A DCD_WRITE • 0x0B0B JUMP_ADDRESS
2	4	ADDRESS	Only relevant for following commands: READ_REGISTER, WRITE_REGISTER, WRITE_FILE, DCD_WRITE, and JUMP_ADDRESS. For READ_REGISTER and WRITE_REGISTER commands, this field is address to a register. For WRITE_FILE and JUMP_ADDRESS commands, this field is an address to internal or external memory address.
6	1	FORMAT	Format of access, 0x8 for 8-bit access, 0x10 for 16-bit and 0x20 for 32-bit access. Only relevant for READ_REGISTER and WRITE_REGISTER commands.
7	4	DATA COUNT	Size of data to read or write. Only relevant for WRITE_FILE, READ_REGISTER, WRITE_REGISTER and DCD_WRITE command. For WRITE_FILE and DCD_WRITE commands DATA COUNT is in byte units.

Table continues on the next page...

Table 19-55. 16 Byte SDP Command Structure (continued)

BYTE Offset	Size	Name	Description
11	4	DATA	Value to write. Only relevant for WRITE_REGISTER command.
15	1	RESERVED	Not used in the device ROM

19.8.3.1 SDP Command

SDP commands are described in the following sections.

19.8.3.1.1 READ REGISTER

The transaction for command READ_REGISTER consists of following: 16 bytes (carried through Report1 in case of USB OTG interface) for command, HAB mode (carried through Report3 in case of USB OTG interface) and response or register value (carried through Report 4 in case of USB OTG interface). The register to read is specified in ADDRESS field of SDP command. First device sends HAB mode (through report-3 in case of USB OTG) followed by data bytes (carried through report-3 in case of USB OTG interface) read at given address. In case of USB OTG interface in use, if count is greater than 64 then multiple reports with report id 4 are sent until entire data requested by host is sent, while in case of other interfaces, the whole data is sent continuously The STATUS is either 0x12343412 for production parts and 0x56787856 for development parts.

Command, Host to Device (carried through Report1 in case of USB-OTG):

Report ID(For USB Only)	16 Bytes SDP Command
1	Valid values for READ_REGISTER COMMAND, ADDRESS, FORMAT, DATA_COUNT

Response, Device to Host:

	Response, Device to Host
3	4 bytes HAB mode indicating Production/Development part

Response, Device to Host: first response report

Report ID(For USB Only)	Response, Device to Host: first response
4	Register Value

If number of bytes requested is less than 4 then remaining bytes should be ignored by host.

In case of USB OTG only, multiple reports of Report ID 4 are sent until entire data requested is sent

Report4, Response, Device to Host: Last response report

Report ID(For USB Only)	Response, Device to Host: Last response report
4	Register Value

If number of bytes requested is less than 64 then remaining bytes should be ignored by host.

19.8.3.1.2 WRITE REGISTER

The transaction for command WRITE_REGISTER consists of following: 16 bytes (carried through Report1 in case of USB OTG interface) for command, HAB mode (carried through Report3 in case of USB OTG interface) and write status (carried through Report4 in case of USB OTG interface). Host sends WRITE_REGISTER command (using Report1 in case of USB OTG interface). The register to write is specified in ADDRESS field of SDP command, with FORMAT field set to data type (number of bits to write 8, 16 or 32) and value to write in DATA field of SDP command. Device writes the DATA to register address and returns WRITE_COMPLETE response code (using Report4 in case of USB OTG interface) and Development/Engineering part status (using Report3 in case of USB OTG interface) to complete the transaction.

Command, Host to Device:

Report ID(For USB only)	Command, Host to Device
1	Valid values for WRITE_REGISTER COMMAND, ADDRESS, FORMAT, DATA_COUNT and DATA

Response, Device to Host:

Report ID(For USB only)	Response, Device to Host
3	4 bytes HAB mode indicating Production/Development part

Response, Device to Host:

Report ID(For USB only)	Response, Device to Host
4	WRITE_COMPLETE (0x128A8A12) status

On failure device will report HAB error status.

19.8.3.1.3 WRITE_FILE

The transaction for command WRITE_FILE consists of following reports: 16 bytes (carried through Report1 in case of USB OTG interface) for command, HAB mode (carried through Report3 in case of USB OTG interface) and write status (carried through Report4 in case of USB OTG interface). Host sends WRITE_FILE command (through Report1 in case of USB OTG interface). The address to write is specified in ADDRESS field of SDP command (of Report1 in case of USB OTG interface), with FORMAT field set to data type (number of bits to write 8, 16, or 32). The data to be written to the address specified in SDP ADDRESS field then follows, from Host to Device (through Report2 in case of USB OTG interface). Device then returns COMPLETE code (using Report4 in case of USB OTG interface) and Development/Engineering part status (using Report3 in case of USB OTG interface) to complete the transaction:

Report1, Command, Host to Device:

Report ID(For USB only)	Command, Host to Device
1	Valid values for WRITE_FILE COMMAND, ADDRESS, DATA_COUNT

=======================Optional Begin=================

Host sends ERROR_STATUS command to query if HAB rejected the address

======================= Optional End==================

Data, Host to Device:

Report ID(For USB Only)	Data, Host to Device
2	File Data

In case of USB OTG interface, Data will be sent through Max 1024 bytes data per report. In case of DATA_COUNT more than 1024 bytes, host sends more Report2, Data, Host to Device:

Report2, Data, Host to Device:

Report ID(For USB only)	Data, Host to Device
2	File Data

Response, Device to Host:

Report ID(For USB only)	Response, Device to Host
3	4 bytes HAB mode indicating Production/Development part

Response, Device to Host:

Report ID(For USB only)	Response, Device to Host
4	COMPLETE (0x88888888) status

On failure device will report HAB error status.

19.8.3.1.4 ERROR_STATUS

The transaction for SDP command ERROR_STATUS consists of three parts. Host sends the command (through Report1 in case of USB OTG interface); device sends global error status in 4 bytes (using Report4 in case of USB OTG interface) after returning Development/Engineering status code (through Report3 in case of USB OTG interface). When device receives ERROR_STATUS command it will return global error status that is updated for each command. This command is useful to find out if last command resulted in device error or succeeded.

Command, Host to Device:

Report ID(For USB only)	Command, Host to Device
1	ERROR_STATUS COMMAND

Response, Device to Host:

Report ID(For USB only)	Response, Device to Host
3	4 bytes HAB mode indicating Production/Development part

Response, Device to Host:

Report ID(For USB only)	Response, Device to Host
4	4 bytes Error Status

19.8.3.1.5 DCD WRITE

The SDP command DCD_WRITE is used by host to send multiple register writes together. This command is provided to speed up the process of programming register writes such as to configure external RAM device. The command (sent through Report1 in case of USB OTG interface) goes with COMMAND TYPE set to DCD_WRITE, ADDRESS which is used for temporary location of DCD data and DATA_COUNT to number of bytes sent in data out phase. In data phase, host sends data for number of registers (using Report2 in case of USB OTG interface). Device completes the transaction (with Report3 in case of USB OTG interface) indicating Development/ Production STATUS and WRITE_COMPLETE (with report 4 in case of USB OTG interface) code 0x12828212.

Command, Host to Device:

Report ID(For USB only)	Command, Host to Device
1	DCD_WRITE COMMAND, ADDRESS, DATA_COUNT

Data, Host to Device:

Report ID(For USB only)	Datam Host to Device
2	DCD binary data

Max 1024 bytes per report in case of USB OTG only.

Response, Device to Host:

Report ID(For USB only)	Response, Device to Host
3	4 bytes HAB mode indicating Production/Development part

Response, Device to Host:

Report ID(For USB only)	Response, Device to Host
4	WRITE_COMPLETE (0x128A8A12) status

On failure device will report HAB error status.

See Device Configuration Data (DCD) for DCD format description.

19.8.3.1.6 JUMP ADDRESS

The SDP command JUMP_ADDRESS will be the last command host can send to the device, after this command device will jump to the address specified in the ADDRESS field of SDP command and start executing. This command should typically follow after WRITE_FILE command. The command is sent by host in command-phase of transaction (using Report1 in case of USB OTG interface), there is no data phase for this command but device send status (through report3 in case of USB OTG interface) to complete the transaction. And if HAB authentication fails then it will also send HAB error status (through report 4 in case of USB OTG interface).

Command, Host to Device:

Report ID(For USB only)	Command, Host to Device
1	JUMP_ADDRESS COMMAND

Response, Device to Host:

Report ID(For USB only)	Response, Device to Host
3	4 bytes HAB mode indicating Production/Development part

Device sends a response only in case of an error jumping to the given address; device reports error with Response, Device to Host:

Report ID(For USB only)	Response, Device to Host
4	4 bytes HAB Error Status

19.9 Recovery Devices

The device ROM supports recovery devices. If primary boot device fails, boot ROM will try to boot from recovery device using one of I2C or SPI ports.

For enabling recovery device BOOT_CFG4 [6] fuse must be set. Additionally Serial EEPROM fuses must be set as described in Serial ROM Boot using SPI/I2C Interface.

19.10 HAB Re-Authentication at Low Power Standby Exit

This feature allows Boot code to be re-authenticated when silicon wakes up after entering low power standby. This Feature is controlled by BOOT_CFG3[0]. When fuse is set then this feature is enabled. During development stage this bit can be controlled using RCON16 (when BOOT_MODE[1:0]=0b10). When BT_FUSE_SEL efuse is blown, then the configuration setting is read from eFUSE. When enabled, the boot code is downloaded again from the boot interface (either Primary or Secondary) based on settings of PERSIST_SECONDARY_BOOT. After downloading the code is then re-authenticated using HAB based on settings of SEC_CONFIG[1:0] eFuse. Authenticated code is then allowed to execute. In case the authentication fails, the Boot ROM tries to download the image from the Recovery Device (depending on settings of BOOT_CFG4[6]). This feature is targeted to prevent execution of any malicious code or accidental modification of boot code that was introduced when the system was under STANDBY state.

19.11 Running Secondary Core

To start execution in the secondary (Cortex-M4) core, an application entry address must be established and the auxiliary core clock must be enabled. The auxiliary core begins execution in the Boot ROM code. The Boot ROM code checks the validity of the application entry address address pointed to by SRC_GPR2 and, if valid, jumps to the address.

1. Set SRC_GPR2[PERSISTENT_ENTRY1] to the entry point for the application to be executed by the secondary core. Ensure that this address is odd because the Cortex-M4 supports only Thumb Mode. For example,

   ```
   SRC.GPR2[PERSISTENT_ENTRY1] = 0x3f040410+1;
   ```

2. Set SRC_GPR3[PERSISTENT_ARG1] to the argument to be passed to the application.
3. Enable the auxiliary core clock by setting CCM_CCOWR to the key number 0x15a5a.

   ```
   CCM_CCOWR = 0x15a5a;
   ```

19.12 Appendix

19.12.1 IOMUX and GPIO Pad Settings for BOOT Interfaces

To view the IOMUX and GPIO Pad settings of Boot interfaces, refer to the BOOT_IOMUX_GPIO_SETTINGS excel file attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the excel file to open it.

19.12.2 Fuse RCON Mapping

To view the RCON pins and Port pin mapping of BOOT interfaces, refer to Fuse_RCON_Mapping excel file attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the excel file to open it.

19.12.3 PLL Configuration after BOOT

Table 19-56. PLL Configuration After Boot

PLL	Main		Fractional Divider 1		Fractional Divider 2		Fractional Divider 3		Fractional Divider 4	
	Mul	Freq (MHz)	Div	Freq (MHz)	Div	Freq (MHz)	Div	Freq (MHz)	Div	Freq (MHz)
PLL1	22	528	19	500.21	21	452.57	24	396	18	528
PLL2	22	528	19	500.21	24	396	28	339.42	23	413.21
PLL3	20	480	28	308.57	26	332.3	29	297.93	29	297.93

NOTE

PLL2 will be disabled after boot. PLLSYS and PLL3 are enabled during boot.

19.12.4 Basic CCM Settings

Table 19-57. CCM_Settings

Register	Value	Description
CCR	0x0001_10FF	FIRC_EN = 1, COSC_EN = 1, OSCNT = 0xFF
CSR	0x0000_0030	COSC_READY = 1
CCSR	0x0004_0824	PLL1_PFD_CLK_SEL = 0x4, PLL1_PFD4_EN = 1, FAST_CLK_SEL = 1, SYS_CLK_SEL = 0x4
CACRR	0x0060_0809	FLEX_CLK_DIV = 1, PLL6_CLK_DIV = 1, IPG_CLK_DIV = 1, BUS_CLK_DIV = 1, ARM_CLK_DIV = 1
CIMR	0xFFFF_FFFF	M_COSC_READY = 1, M_LRF_PLL4 = 1, M_LRF_PLL3 = 1, M_LRF_PLL2 = 1, M_LRF_PLL1 = 1

Chapter 20
Debug Architecture

20.1 Overview

This document describes the hardware and software debug and application development features and resources of this device.

The device debug and trace is based on ARM CoreSight architecture supplemented with the Secured JTAG controller (SJC) to allow security features.

1. Supports IEEE 1149.1 JTAG, IEEE 1149.7 JTAG, and ARM Serial Wire Debug (SWD) interface.
2. A range of security levels from NO JTAG to fully Open based on eFuse configuration for both debug and Test.
3. Support for Secured and non secured invasive/ non invasive debug to allow further granularity in debug accesses.
4. Support for field return parts to open access for debug and test to allow failure analysis.
5. Cross Trigger supported between the two cores as recommended by ARM.
6. Following debug capabilities are supported:
    a. Access to core and memory mapped resource examination and modification.
    b. Support for monitor mode and halt mode.
    c. Breakpoint/ Watchpoint control.
7. System profiling and performance monitoring.
8. CoreSight Embedded Trace Macrocell (ETM) and Instrumentation Trace Macrocell (ITM) to generate traces from the Cortex A5 and Cortex M4 cores.

9. Support ARM Real Time trace Interfaces: Trace Port Interface Unit (TPIU) and Serial Wire Output (SWO).
10. For TPIU trace port the maximum trace packets extraction bandwidth is limited by the pads and is equal to 160MByte/s (80Mhz x 16-bit).
11. For SWO the maximum frequency of operation is targeted for 24Mhz.

20.2 System Level Debug Architecture

This section discusses the overall debug and trace architecture from system perspective. The figure below gives the overall block diagram and design topology of the debug architecture.

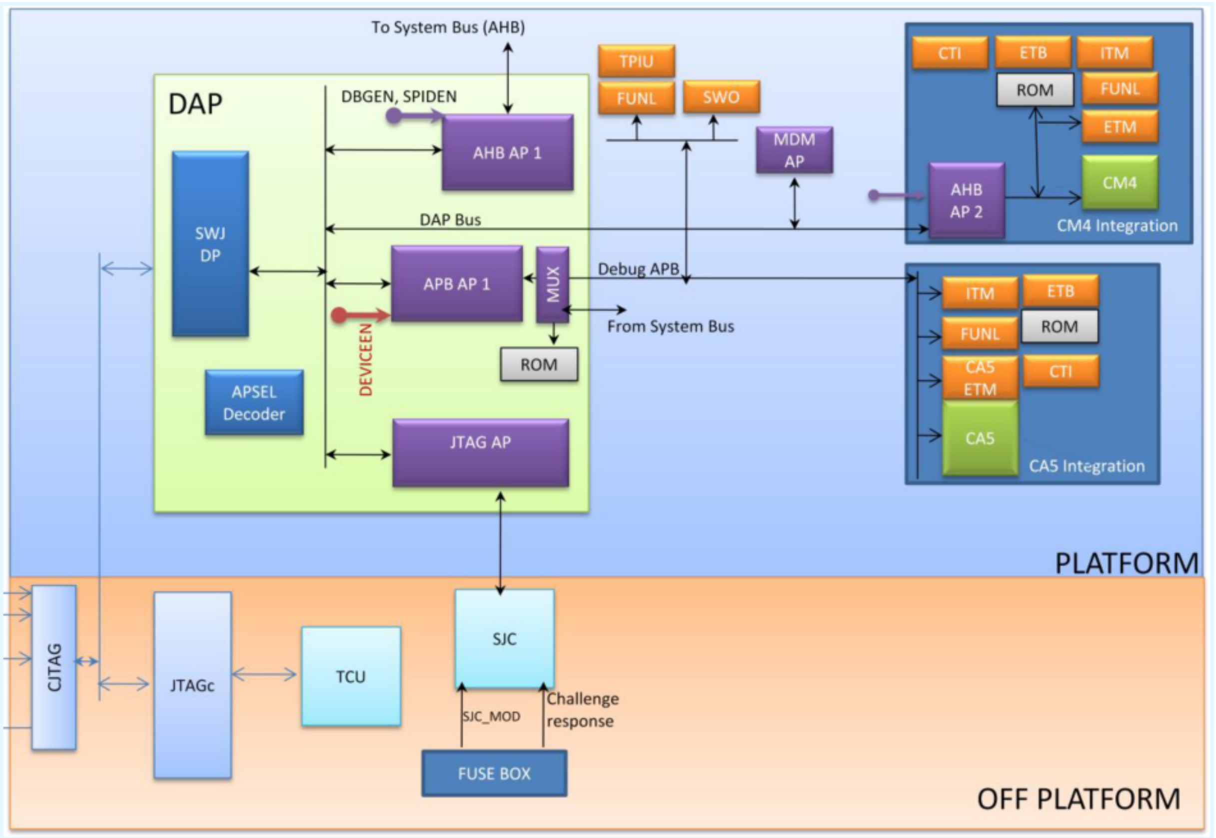

Figure 20-1. Debug Architecture Block Diagram

All ARM specific debug logic – Debug Access Port (DAP) and trace modules are integrated in the platform. The term platform is just a design partition consisting of cores integration, interconnect, debug, DMA, OCRAM controllers and a few other blocks.

The access to core and memory mapped resources is based on DAP. The access is controlled by security level configuration and authentication using the (Secure JTAG Controller) SJC block. SJC is accessible through the JTAG Access Port (JTAG AP) of DAP.

If the device is in fab or is a field return (both conditions set by way of eFuse configuration) all accesses to core/ memory mapped resources are fully available else these accesses are subject to authentication using SJC.

The TCU is fully accessible in fab and for field return; else it is completely blocked for security reasons.

The JTAGc is *always* available to allow boundary scan.

The debug IDCODE in case of JTAG DP is 0x4BA00477 and in case of SW DP it is 0x3BA02477.

20.3 Test and Debug Access Port Connectivity

The figure below gives a detailed TAP connectivity diagram.

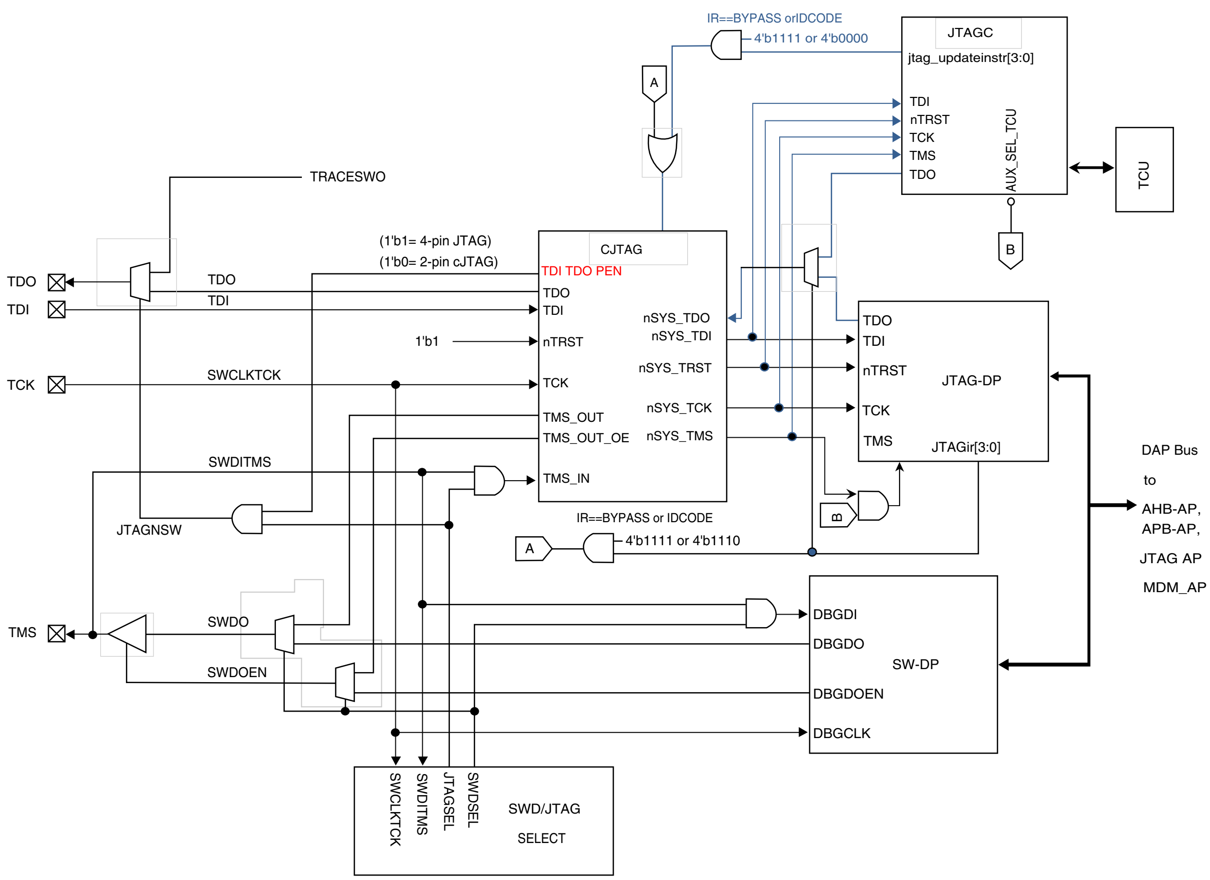

Figure 20-2. Detailed TAP connectivity diagram

In Figure 20-2 the *SWD/JTAG SELECT, SW-DP* and *JTAG-DP* are part of *ARM DAP*.

Please note the following points from Figure 20-2 :

1. The Debug port comes out of reset in a standard 4 wire JTAG mode only. It is switched into SWD or cJTAG mode by change sequences described in JTAG-to-SWD change sequence and JTAG-to-cJTAG change sequence. Once the mode has been changed, unused debug pins can be reassigned to any of their alternative muxed functions. Once switched to C-JTAG or SWD, switching back to 4-Wire JTAG is not possible.
2. The JTAG pads are connected to cJTAG as the primary interface. Besides the TMS is also observed by the SWD/ JTAG switcher logic of the DAP (*SWDITMS* input in *SWD/JTAG SELECT block*).
3. The JTAG DP and JTAGC are connected to cJTAG in an *overlay scheme*; both have an IR length of *four*.
4. The TCU is an auxiliary TAP on the JTAGC.
5. If TCU is selected *(AUX_SEL_TCU goes HIGH),* the TMS input for the JTAG-DP is driven LOW (Refer to connector "B" in the diagram). Thus giving exclusive access to the auxiliary TAP (this allows auxiliary TAP to have an IR length greater than four).
6. If the DAP switches from JTAG to SWD (when SWD/ JTAG SELECT receives the switching sequence), the TMSIN for cJTAG is driven low (as JTAGSEL goes LOW) and the TMS pad is used for SWD data inout.

20.4 JTAG to SWD cJTAG switching sequence

20.4.1 JTAG-to-SWD change sequence

- Send more than 50 TCK cycles with TMS(SWDIO) =1
- Send the 16-bit sequence on TMS(SWDIO) = 0111_1001_1110_0111 (MSB transmitted first)
- Send more than 50 TCK cycles with TMS (SWDIO) =1.

  This is shown in the Figure 20-3.

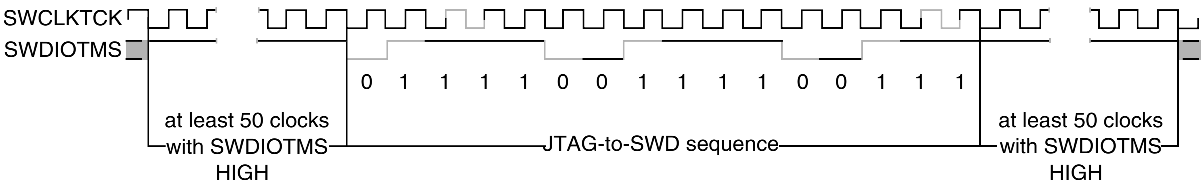

Figure 20-3. JTAG-to-SWD switching sequence

20.4.2 JTAG-to-cJTAG change sequence

- Reset the debug port.
- Set the control level to 2 via the zero-bit scans.
- Execute the Store Format (STFMT) command (00011) to set the scan format register to 1149.7 scan format.

20.4.3 System JTAG Controller (JTAGC)

The system JTAG controller (JTAGC) is connected in parallel with ARM TAP controller (JTAG DP of ARM DAP). The IR length is 4-bits. The JTAGC IR codes overlay the ARM DAP controller IR codes. JTAGC uses *twelve* instructions and the DAP uses rest *four*. The outputs of the TAPs (TDO) are muxed based on the IR Code which is selected. This design is fully JTAG compliant and appears to the JTAG chain as a single TAP.

The Table 20-1 gives the IR codes for the system JTAG controller. For the instructions used by ARM DAP TAP refer to Table 20-2.

Table 20-1. JTAG instructions for system JTAG controller (JTAGc)

Code	JTAGC IR
4'b0000	IDCODE
4'b0001	CENSOR_CTRL
4'b0010	SAMPLE-PRELOAD
4'b0011	SAMPLE
4'b0100	EXTEST
4'b0101	HI-Z
4'b0110	TEST_CTRL
4'b0111	TEST_LEAKAGE
4'b1000	*Not used by JTAGC (used by DAP)*
4'b1001	AUX ACCESS 1 (TCU selection)
4'b1010	*Not used by JTAGC (used by DAP)*

Table continues on the next page...

Table 20-1. JTAG instructions for system JTAG controller (JTAGc) (continued)

Code	JTAGC IR
4'b1011	*Not used by JTAGC (used by DAP)*
4'b1100	Reserved
4'b1101	CLAMP
4'b1110	*Not used by JTAGC (used by DAP)*
4'b1111	BYPASS

The Test Control Unit (TCU) is an auxiliary TAP on the JTAGc. It is selected by the instruction "AUX ACCESS 1". When TCU is selected the DAP JTAG DP is disconnected (TMS input to JTAG DP goes low), giving TCU exclusive access of the JTAG port. Refer to id-_Ref302467261. DFT Specification for details related to TCU.

20.4.4 Debug Access Port (DAP) TAP

DAP is a standard ARM component. The DAP provides multiple master driving ports, all accessible and controlled through a single external interface port to provide system-wide debug.

As discussed earlier the DAP IR overlay with the system JTAG controller IR. The DAP Instruction Registers is listed in Table 20-2.

DAP uses five Instructions but since BYPASS is identical with JTAGC it has been dropped out.

Table 20-2. ARM DAP IR Codes

Code	DAP IR
4'b1000	ABORT
4'b1010	DPACC
4'b1011	APACC
4'b1110	IDCODE

The DAP offers AHB and APB master interfaces to access system buses. It also exports the internal DAP bus to allow to extend the access ports as per the system requirement. It offers JTAG AP to allow adding auxiliary TAPs. The device uses JTAG AP to connect the Secure JTAG controller (SJC) block as an auxiliary TAP. For more details on SJC refer to id-_Ref302670360. For more information on DAP TAP refer to ARM Debug Interface v5 Architecture specification [id-_Ref302468262].

The AHB AP provides the debugger access to all memory and registers in the system. System access is independent of the processor status. AHB-AP does not do back to back transactions on the bus, so all transactions are non sequential.

The APB AP is used to access the CoreSight components for the CA5 and also the shared debug components of the system trace like TPIU, SWO.

The exported DAP bus is used to host AHB AP access port (integrated as part CM4 integration) and the Miscellaneous Debug module Access Port (MDM AP).

The MDM AP hosts system level JTAG status and control registers (refer to Debug Status and Control Registers) which can be used for cross triggering, synchronized debug, low power and other misc control/ status.

The selection of different access ports in the DAP is done based on the APSEL value set in the SELECT register of SWJ-DP. APSEL is 31:24 bit field of the DAP SELECT register.

The APSEL will be decoded as given in Table 20-3.

Table 20-3. APSEL decode

APSEL (SELECT[31:24])	Selection	Identification Register (IDR) value
8'h00	AHB-AP to System Bus (NIC-301)	0x4477_0001
8'h01	APB-AP to "Shared" debug IP and CA5 debug IP	0x2477_0002
8'h02	JTAG-AP to SJC	0x1476_0010
8'h03	AHB-AP to CM4	0x2477_0011
8'h04	Miscellaneous Debug module AP (MDM-AP)	0x001C_0000
8'hø5- 8'hff	Reserved (Default AP response)	-

20.4.4.1 ROM Table

The ROM table is used to hold the information about the debug components.

There are three ROM tables.

1. The CM4 ROM table resides on the AHB AP2 and has entries for CM4 debug components.

2. The DAP ROM table resides on the APB AP. It has entries for the common trace components, MDM AP and the last entry points to the CA5 ROM table. The DAP ROM table last entry has a "valid" bit (bit-0 in the ROM table entry). When this bit is "0", the last entry returns 0x00000000. When this bit is "1" the last entry returns the pointer to CA5 ROM table.
3. The CA5 ROM Table resides on APB AP. This has entries for CA5 debug components.

Table 20-4. ROM Table Entries bit assignment

Bits	Name	Description
[31:12]	Address offset	Base address of the component, relative to the ROM address. Negative values are permitted using two's complement. ComponentAddress = ROMAddress + (AddressOffset SHL 12).
[11:2]	-	Reserved SBZ.
[1]	Format	1 = 32-bit format. In the DAP Debug ROM this is set to 1. 0 = 8-bit format.
[0]	Entry present	Set HIGH to indicate an entry is present.

The device supports three core configurations:

1. Both CA5 and CM4 are present: All ROM tables are accessible and "valid" bit is set.
2. CM4 only: CM4 and DAP ROM tables are accessible. DAP ROM table "valid" bit is cleared and hence CA5 ROM table is not accessible.
3. CA5 Only: DAP ROM table is accessible and the "valid" bit is set, so CA5 ROM table is accessible. In this case the CM4 ROM table is not accessible.

   Note for Implementation: In case of "CA5 only" the clock for the CM4 should be gated and the DBGEN/ SPIDEN for the AHB AP2 in CM4 integration should be held LOW.

20.4.4.1.1 CM4 ROM table

20.5 Debug Port Pin Descriptions

The debug port pins default after reset to their JTAG functionality and can be later reassigned to their alternate functionalities. In cJTAG and SWD modes TDI can be configured to alternate GPIO functions. Refer to Table 20-5 for pin assignments in different modes.

Table 20-5. Debug Port Pins

Pin Name	JTAG Debug Port		cJTAG Debug Port		SWD Debug Port		Internal Pullup/Down
	Type	Description	Type	Description	Type	Description	
TMS/SWDIO	I/O	JTAG Test mode selection	I/O	cJTAG Data	I/O	Serial Wire Data	Pull-up
TCK/SWCLK	I	JTAG Test clock	I	cJTAG Clock	I	Serial wire clock	Pull-down
TDI	I	JTAG Test Data input	-	-	-	-	Pull-up
TDO/TRACESWO	O	JTAG Test Data output	O	Trace output over a single pin	O	Trace output over a single pin	NC

20.6 Secure JTAG Controller (SJC)

SJC is accessed through the JTAG AP of the DAP. The SJC has a 5-bit Instruction Register which is described in Table 20-6.

Table 20-6. System JTAG Controller Instruction Registers

Code	SJC IR
5'b00000 - 5'b00011	Reserved
5'b00100	Enable Extra misc registers
5'b00101 - 5'b01011	Reserved
5'b01100	Security Output Challenge
5'b01101	Security input response
5'b01110 – 5'b11110	Reserved
5'b11111	BYPASS

The Extra misc registers IR allows accessing the extra miscellaneous registers. These include the register to understand the status of the authentication in case of challenge/ response. There can be other uses of these registers which the SOC can define.

The Security Output Challenge and Security Input Response IRs allows the debugger to read the security challenge and feed the response for authentication in case the Challenge-Response based authentication is in place. For details of the SJC block refer to System JTAG Controller (SJC) chapter.

The various security level configurations are discussed in section *Secured JTAG*.

20.6.1 Challenge Response Access Sequence

When JTAG_SMODE is 2'b01 (Secure JTAG mode is enabled), Fuse SJC_CHALL[63:0] and SJC_RESP[53:0] would have programmed. Now following steps need to follow to pass the challenge response.

1. Program SPIDEN and SPNIDEN in SRC_SECR_DOUT register through Software (if secured traces are required: this is possible only for authenticated software running in secured world).

2. PowerUp DAP

3. Select Port 0 for SJC in JTAG-AP PORT SELECT registers.

4. Reset SJC TAP by writing into JTAG-AP CSW register. Set TRST_OUT = 1. Also set TMS High for 5 clocks in BWFIFO 1 register change the bank select. After some random delay, release TRST_OUT.

5. Move SJC TAP to IDLE state.

6. Shift in the Challenge Instruction.

7. Read out the challenge Value.

8. Shift IR RESPONSE Instruction.

9. Shift DR Response 56 bit value.

10. READ MDM AP STATUS Register if Debug Enable bit is Set and Secure Debug bit is set

If the First attempt with Incorrect Challenge Response results into failure, subsequent attempts of correct Challenge Response will still be discarded. Only POR reset will let Debugger start the attempts from beginning.

20.7 Debug Status and Control Registers

The debugger has access to the status and control elements, implemented as registers in MDM-AP on the DAP bus as shown in Figure 20-1. These registers provide additional control and status for low power mode recovery and typical run-control scenarios. The status register bits also provide a means for the debugger to get updated status of the core without having to initiate a bus transaction across the crossbar switch, thus remaining less intrusive during a debug session.

It is important to note that these DAP control and status registers are not memory mapped within the system memory map and are only accessible via the Debug Access Port (DAP) using JTAG, cJTAG, or SWD. The MDM-AP is accessible as Debug Access Port 4 (refer to Table 20-3). The MDM-AP registers are listed in Table 20-7.

Table 20-7. MDM-AP Register Summary

Address	Register	Description
0x0400_0000	Status	MDM AP Status Register (Refer Table 20-9)
0x0400_0004	Control	MDM AP Control Register (Refer Table 20-8)
0x0400_00FC	ID	Read only Identification register that always reads as 0x001C_0000

20.7.1 Miscellaneous Debug Module (MDM) AP Control Register

The debugger can write to MDM-AP control register only if the DBGEN is SET ie the debugger security authentication has been cleared. In case the debugger makes an access while DBGEN=0, the access will be simply ignored and no error will be reported.

Table 20-8. MDM AP Control Register Assignments

Bit	Name	Description
0-1	Reserved	Not used
2	CM4 Debug Request	Drives "EDBGREQ" input for CM4. When the core goes into debug state it acknowledges with "HALTED" output signal. If the core is in STOP mode this bit is used to wake-up the core and transition to halted state.
3	System reset request (SYSRESETREQ)	Set to force the system reset. The system remains in reset till this bit remains asserted. When this bit is reset the entire system comes out of reset.
4	Reserved	unused

Table continues on the next page...

Table 20-8. MDM AP Control Register Assignments (continued)

Bit	Name	Description
5	Standby mode debug request (STANDBYDBGREQ)	Set to configure the system to be held in reset after the next recovery from standby modes (LPSTOP1/2/3). This bit is sampled by the SRC as "HOLD reset latch" just before the GPC moves the part in any of the LPSTOP modes and remains latched in always ON domain during the standby phase. On exit from standby mode SRC holds the CM4 and CA5 in reset at the end of system reset sequencing until hold reset release is asserted. The STANDBYDDBREQ is cleared due to POR reset generated as part of LPSTOP recovery.
6	Standby mode debug acknowledge (STANDBYDBGACK)	Set to release the cores being held in reset following a standby recovery due to SRC "HOLD reset latch". This bit drives directly the SRC to control this feature. Besides this bit also clears the "standby mode exit" status bit. The debugger re-initializes all debug IP and then asserts this control bit to allow the SRC to release the cores from reset and allow CPU operation to begin. The STANDBYDBGACK bit is cleared by JTAG or clears automatically due to POR reset generated as part of standby recovery.
7	Reserved	Unused
8	Timestamp disable	Freeze Time stamp during HALT mode. 0: The timestamp counter continues to count when the core is halted. 1: The timestamp counter freezes when either of the cores is halted. This allows to avoid generation of generation of timestamp overflow messages when the core is halted.
9	Inhibit Sleep	This bit is monitored by the power controller. If set the device will not move into power gated mode. Thus debugger can make safe accesses without risk of losing communication due to debug logic going into power down.
10-17	Reserved	Unused
18	CA5 Debug Request	Drives "EDBGREQ" input for CA5. When the core goes into debug state it acknowledges with "HALTED" output signal. If the core is in STOP mode this bit is used to wake-up the core and transition to halted state.
19-23	Reserved	unused
24	CTI trigger input	Connects to CTI trigger input
25	CTI trigger output ack Reserved	Acknowledgement for the CTI trigger out received on bit-22 of the MDM-AP status register. TKT085997 : fix postponed.
26-29	Reserved	unused
30	CM4 debug restart	CM4 debug restart input to CM4 core.
31	CA5 debug restart	CA5 debug restart input to CA5 core.

20.7.2 Miscellaneous Debug Module (MDM) AP Status Register

Table 20-9. MDM-AP Status Register Assignments

Bit	Name	Description
0-1	Reserved	Not used
2	System reset	Indicates the system reset state 1: system not in reset 0: system is in reset
3	debug access enable	Indicates if the debugger can access to AHB and APB AP. This bit reflects the status of DBGEN (which is same as NIDEN).
4	debug secured access enable	Indicates if the debugger can make secured accesses to the debug logic and can trace out secured traces. This bit reflects the status of SPIDEN/ SPNIDEN. SPIDEN and SPNIDEN are same and are controlled by configurable bit by secured software.
5-9	Reserved	Not used
10	Standby mode exit	This bit indicates an exit from standby mode has occurred. The debugger had lost communication while the system is in standby mode (including access to this register). Once communication is reestablished, this bit indicates that the system had been standby mode. Since the debug modules lose their state during standby mode, they need to be reconfigured. This bit is implemented in SoC glue logic and is set during the standby mode recovery sequence. The standby Mode Exit bit is held until the debugger has had a chance to recognize that a standby mode was exited and is cleared by a write of 1 to the STANDBYDBGACK bit[6] in MDM AP Control register.
11-15	Reserved	Not used
16	CM4 Halted	CM4 has entered debug halt mode
17	CM4 SLEEPDEEP	CM4 asserted SLEEPDEEP
18	CM4 SLEEPING	CM4 asserted SLEEPING
19	CA5 halted	CA5 has entered debug halt mode
20	CA5 STANDBYWFI	
21	CA5 STANDBYWFE	
22	CTI trigger out	Cross Trigger Interface Trigger out asserted.
23-29	Reserved	unused
30	CM4 debug restarted	Debug restarted output status from CM4.
31	CA5 debug restarted	Debug restarted output status from CA5.

Note for Implementation: The MDM-AP control register is accessible only after debug authentication. The MDM-AP status register is always accessible.

20.8 Debug Resets

The debug system receives the following sources of reset:

- Debug reset (CDBGRSTREQ bit within the SWJ-DP CTRL/STAT register) in the TCLK domain that allows the debugger to *reset the debug logic*. This includes ATRESETn for cm4_atbasync, csfunnel, csreplicator, csswo, cstpiu, CSATBUPSIZER_etm, CSATBUPSIZER_itm, CSREPLICATOR, CSETB, ca5_itm_upsizer) AND PRESETDBGn for csfunnel, csswo, cstpiu, DAP APs, faraday_dbg_trace_ctrl, CSTFUNNEL, CSETB, CSCTI, ca5_itm, ca5_funnel, ca5_etb.
- System POR reset.

Conversely the debug system is capable of generating system reset using the following mechanism:

- A system reset in the MDM-AP control register which allows the debugger to hold the *system* in reset.

20.9 Trace Architecture

The figure below shows the trace architecture for the device.

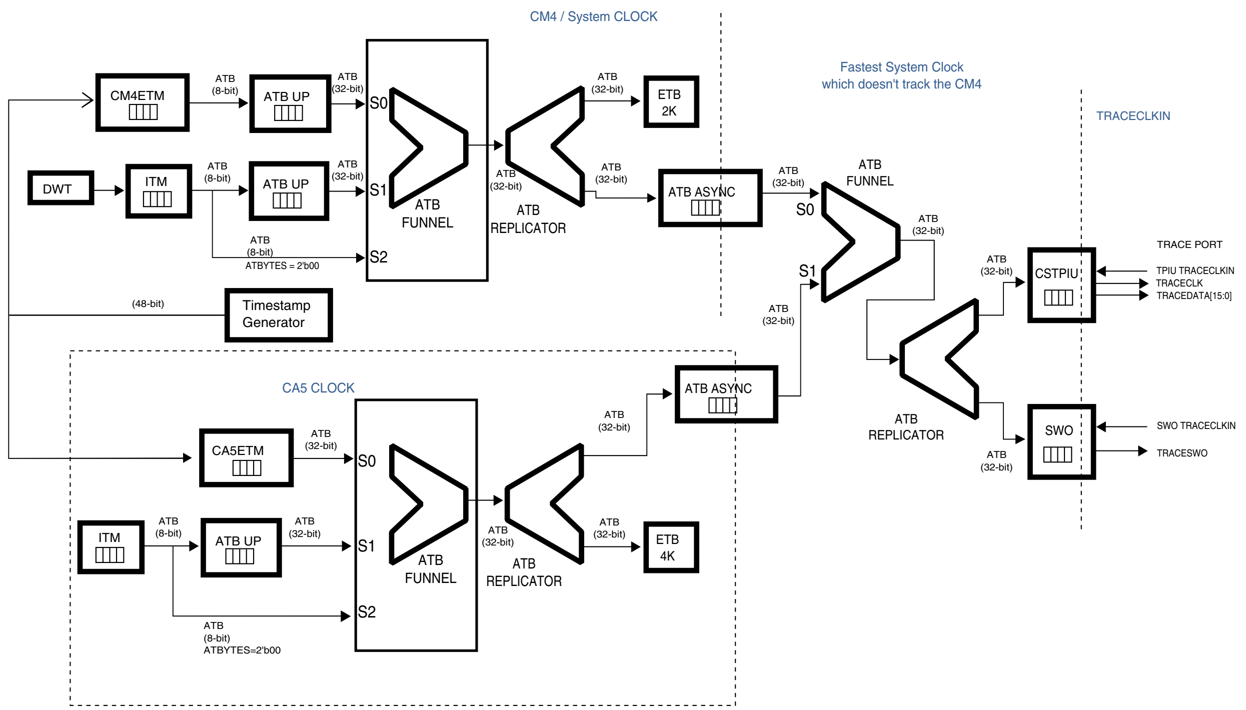

Figure 20-4. Trace Bus Connectivity diagram

The following Trace Paths are supported:

- Trace paths on a Cortex-M4 only device:

CM4 ATB path to TPIU enabled, CA5 ATB path to disabled to ensure that the CA5 ATB isn't requesting a transaction

- Trace paths on a Cortex-A5 only device:

CM4 ATB path to TPIU disabled, CA5 ATB path to enabled to ensure that the CM4 ATB isn't requesting a transaction.

- Trace paths on a dual-core device:

a) CM4 ETM/ITM to ETB and CA5 ETM/ITM to ETB. The TPIU is disabled; both trace path disable bits can be left enabled (or disabled).

b) CM4 ETM/ITM to TPIU and CA5 ETM/ITM to TPIU. Both trace paths (CM4 ATB Path and CA5 ATB path) enabled.

c) CM4 ETM/ITM to ETB and CA5 ETM/ITM to TPIU. The trace path from the CM4 to TPIU must be disabled.(CM4 ATB path to TPIU disabled, CA5 ATB path to enabled)

d) CM4 ETM/ITM to TPIU and CA5 ETM/ITM to ETB. The trace path from the CA5 to TPIU must be disabled. (CM4 ATB path to TPIU enabled, CA5 ATB path to disabled)

In case SWO is enabled as the output port, the possible trace paths are

a) CA5 ITM -> CA5 ATB FUNNELS2 -> CA5 ATB REPL -> ATB ASYNC -> shared ATB funnel -> shared ATB RELP -> SWO (in this path only LSByte of the ATB data bus is used)

b) CM4 ITM -> CM4 ATB FUNNELS2 -> CM4 ATB REPL -> ATB ASYNC -> shared ATB funnel -> shared ATB RELP -> SWO (in this path only LSByte of the ATB data bus is used)

c) We can have traces from both CA5 and CM4 ITMs active and these merged by shared ATB funnel and traced out to SWO.

d) One of path a) or b) active while the other core traces logged to the corresponding ETB.

Note

There are *four* clock domains in the trace connectivity. The trace components associated with the CM4 and CA5 work in respective core clock domains. These are separated from the common trace components at the system level through ATB Async interfaces. This allows us to clock the common

components at a fixed high frequency clock (limited by the pad frequency) thereby offering highest possible output bandwidth for draining out the traces, independent of the core frequencies. The TRACECLKIN is driven internally from a mux select from different sources and feeds both TPIU and SWO.

The Platform Trace Control (Pltf-TCTL) module controls the trace flow: The register is at the offset 0x4009_3000 with the following fields:

- Ctrl[0] = CM4 to TPIU Disable
- Ctrl[1] = CA5 to TPIU Disable
- Ctrl[2] = CM4ITM to SWO Enable
- Ctrl[3] = CM5ITM to SWO Enable

20.9.1 Data Watchpoint and Trace (DWT)

DWT is part of *Cortex M4 trace connectivity only*. The DWT is a unit that performs the following debug functionality:

- It contains four comparators that you can configure as a hardware watchpoint, an ETM trigger, a PC sampler event trigger, or a data address sampler event trigger. The first comparator, DWT_COMP0, can also compare against the clock cycle counter, CYCCNT. The second comparator, DWT_COMP1, can also be used as a data comparator.
- The DWT contains counters for:
  - Clock cycles (CYCCNT)
  - Folded instructions
  - Load store unit (LSU) operations
  - Sleep cycles
  - CPI (all instruction cycles except for the first cycle)
  - Interrupt overhead

20.9.2 Flash Patch and Breakpoints (FPB) (CM4 only)

The FPB implements hardware breakpoints and patches code and data from code space to system space. This is applicable to *CM4 core only*.

The FPB unit contains two literal comparators for matching against literal loads from Code space, and remapping to a corresponding area in System space.

The FBP also contains six instruction comparators for matching against instruction fetches from Code space, and remapping to a corresponding area in System space. Alternatively, the six instruction comparators can individually configure the comparators to return a Breakpoint Instruction (BKPT) to the processor core on a match, so providing hardware breakpoint capability.

20.9.3 Instrumentation Trace Macrocell (ITM)

The ITM is an application-driven trace source that supports printf style debugging to trace Operating System (OS) and application events, and emits diagnostic system information. The ITM emits trace information as packets. There are three sources that can generate packets. If multiple sources generate packets at the same time, the ITM arbitrates the order in which packets are output.

The three sources in decreasing order of priority are:

1. Software trace -- Software can write directly to ITM stimulus registers. This emits packets.
2. Hardware trace -- The DWT generates these packets, and the ITM emits them (not supported by CA5 ITM)
3. Time stamping -- Timestamps are emitted relative to packets. The ITM contains a 21-bit counter to generate the timestamp. The Cortex-M4 clock or the bit clock rate of the Serial Wire Viewer (SWV) output clocks the counter.

20.9.4 Embedded Trace Macrocell (ETM)

The ETM v3.5 is supported. The Cortex-M4 Embedded Trace Macrocell (ETM-M4) is a debug component that enables a debugger to reconstruct program execution. The CoreSight ETM-M4 supports only instruction trace. You can use it either with the Cortex-M4 Trace Port Interface Unit (M4-TPIU), or with the CoreSight ETB.

The main features of an ETM are:

- tracing of 16-bit and 32-bit Thumb instructions
- four EmbeddedICE watchpoint inputs
- a Trace Start/Stop block with EmbeddedICE inputs

- one reduced function counter
- two external inputs
- a 24-byte FIFO queue (cortex M4).
- global timestamping

20.9.5 CoreSight Embedded Trace Buffer (ETB)

The ETB provides on-chip storage of trace data using 32-bit RAM. The ETB accepts trace data from any CoreSight-compliant component trace source with an ATB master port, such as a trace source or a trace funnel. It is included in this device to remove dependencies from the trace pin pad speed, and enable low cost trace solutions. The device has two ETBs – one each for CM4 and CA5 traces. The ETB for collecting CM4 traces is 2KB while the one to collect CA5 traces is 4KB.

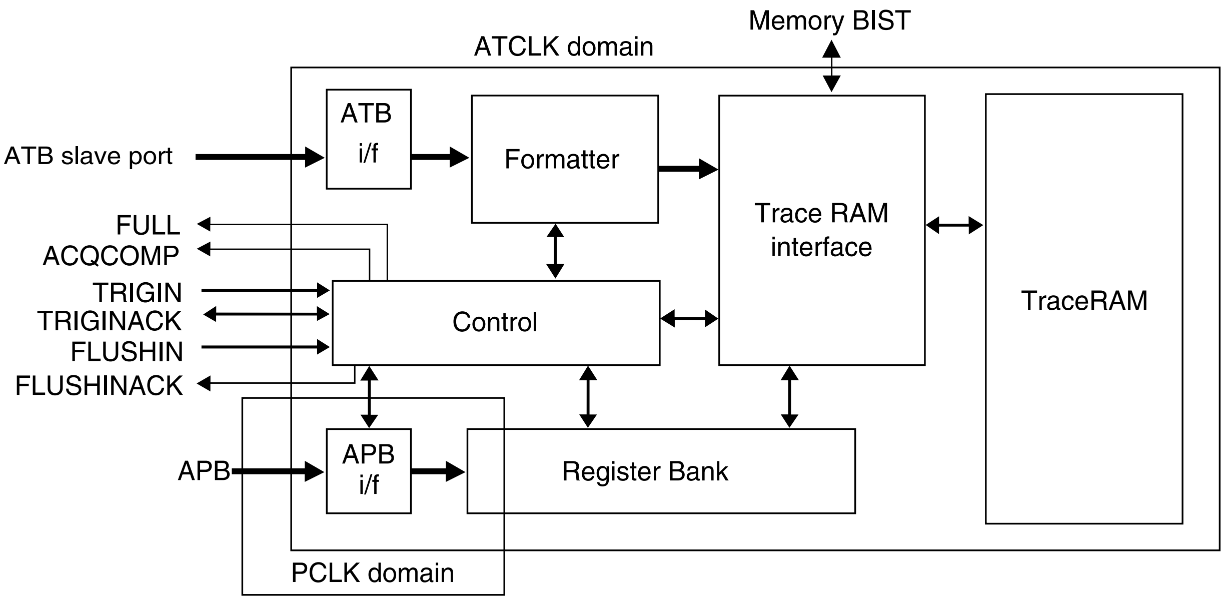

Figure 20-5. ETB Block Diagram

The ETB contains the following blocks:

- Formatter -- Inserts source ID signals into the data packet stream so that trace data can be re-associated with its trace source after the data is read back out of the ETB.
- Control -- Control registers for trace capture and flushing.
- APB interface -- Read, write, and data pointers provide access to ETB registers. In addition, the APB interface supports wait states through the use of a PREADYDBG signal output by the ETB. The APB interface is synchronous to the ATB domain.

- Register bank -- Contains the management, control, and status registers for triggers, flushing behavior, and external control.
- Trace RAM interface -- Controls reads and writes to the Trace RAM..

20.9.6 Trace Port Interface Unit (TPIU)

TPIU acts as a bridge between the on chip trace data from ETM and ITM, with separate IDs to a data stream encapsulating IDs where required to provide external visibility of the packet stream to a Trace Port analyzer. The device offers a synchronous trace port consisting of 16-bit TRACEDATA, TRACECTL and TRACECLK.

20.9.7 Serial Wire Output

The CoreSight SWO is a trace data drain that acts as a bridge between the on-chip trace data to a data stream that is captured by a *Trace Port Analyzer* (TPA). The device also offers an asynchronous Serial Wire out (TRACESWO) interface. The SWO can work at a maximum frequency of 24Mhz.

20.9.8 Performance Monitoring Unit (for CA5 Only)

Each core in the Cortex-A5 MPCore processor contains a PMU which provides two counters to gather statistics on the operation of the core and memory system. Each counter can count any of the events available in the Cortex-A5 MPCore processor. It also provides a single 32-bit cycle counter with support for scaling and filtering on the processor mode and security state. See the *ARM Architecture Reference Manual, ARMv7-A* and *ARM ArchitectureReference Manual Performance Monitors v2 Supplement* for more information about performance monitoring.

20.9.9 Embedded Cross Trigger

Embedded Cross Trigger (ECT) is used for multi core run control and trace cross triggering for example synchronous stop start for all cores or trigger program trace on a trigger event from another core or IP.

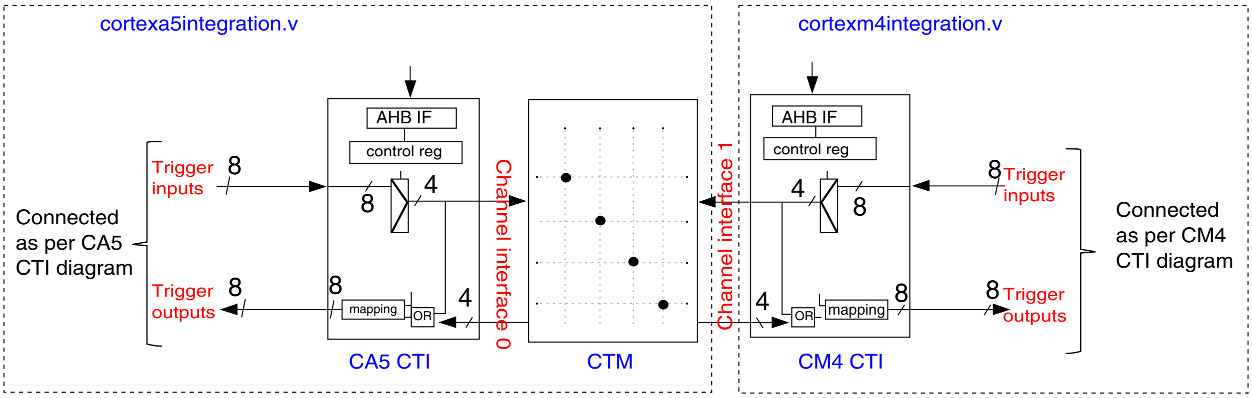
ECT is made up of Cross Trigger Interfaces (CTI) and Cross Trigger Matrix (CTM).

Cross Trigger Interface (CTI) provided by ARM:

- 8 trigger inputs, 8 trigger outputs, basic signal conditioning
- Programmable channel routing (mapping trigger inputs to channels and channels to trigger output.
- Limited to 4 channels

Cross Trigger Matrix (CTM) provided by ARM:

- Provides channel routing when more than 2 CTIs are used.
- Limited to 4 channels



Note: Channel Interface 2 and 3 are unused.

20.9.9.1 CM4 CTI Triggers

CM4 CTI Trigger Inputs:

Table 20-10. CM4 CTI Trigger inputs

Trigger Bit	Source Signal	Source Device
[7]	ETMTRIGOUT	ETM
[6]	ETMTRIGGER[2]	DWT
[5]	ETMTRIGGER[1]	DWT
[4]	ETMTRIGGER[0]	DWT
[3]	ACQCOMP	ETB
[2]	FULL	ETB
[1]	MDMAP CTITRIGIN (MDM-AP Control[24])	MDM-AP
[0]	DBGACK	Core

CM4 CTI Trigger Outputs:

Table 20-11. CM4 CTI Trigger outputs

Trigger Bit	Source Signal	Source Device
[7]	DBGRESTART (This bit is ORed with the CM4 debug restart bit from MDM-AP control register before connected as input to the core)	core
[6]	MDMAP CTITRIGOUT (MDM-AP status[22]) The ack is driven by MDM AP trigout ack(MDM-AP Control[25].	MDM-AP
[5]	ETMEXTIN[1]	ETM
[4]	ETMEXTIN[0]	ETM
[3]	NVIC IntID[5]	NVIC
[2]	Not used	-
[1]	INTISR[x]	NVIC
[0]	EDBGRQ	Core

20.9.9.2 CA5 CTI Triggers

CA5 CTI Trigger Inputs:

Table 20-12. CA5 Trigger Inputs

Trigger Bit	Source Signal	Source Device
[7]	Not used (tied to 1'b0)	-
[6]	TRIGGER	ETM
[5]	COMMRX = ctiasicctl0_o[5] ? etb_acqcomp : commrx[0]	Core
[4]	COMMTX = ctiasicctl0_o[4] ? etb_full : commtx[0]	Core
[3]	EXTOUT[1]	ETM
[2]	EXTOUT[0]	ETM
[1]	PMUIRQ[n]	Core
[0]	DBGTRIGGER[n]	Core

For CA5 CTI trigin[5:4] the select used for mux control "ctiasicctl[5:4]" is the "ASICCTL[5:4]" provided by the CTI.

CA5 CTI Trigger Outputs:

Table 20-13. CA5 Trigger Outputs

Trigger Bit	Source Signal	Source Device
[7]	DBGRESTRAT (This bit is ORed with the CA5 debug restart bit from MDM-AP control register before connected as input to the core)	Core
[6]	GIC IntID[37]	Core
[5]	Not used	-
[4]	EXTIN[3]	ETM
[3]	EXTIN[2]	ETM
[2]	EXTIN[1]	ETM
[1]	EXTIN[0]	ETM
[0]	EDBGRQ[n]	Core

20.10 Low Power Debug

The device supports two types of low power modes:

1. Module clock gating (STOP mode): If the debug power up request, CxxxPWRUPREQ is high and the system *attempts to enter STOP mode*, the DAP clock and the FCLK continue to run to support core register access and trace. In this case the debug module will have access to core registers but not modules which are clock gated.

   If the device *is in STOP mode*, the debugger can assert the EDBGREQ by writing to the MDM-AP control bits (CM4 Debug Request and CA5 Debug Request). This will wakeup the core and it will move to halted state.

2. Power gated mode (LPSTOP1/2/3): When the device goes into power gated mode the device debug logic is also powered off. The debugger cannot gather any debug data for the duration of low power mode.

   If the device is expected to enter into the power gated mode and the debugger wants to restore debug on recovery, the debugger sets bit[5] of MDM-AP control register (STANDBYDBGREQ).

   The debugger continues to try to reestablish connection to the debug port while the device is in power gated mode. Once the device exits power gated mode, this status is available in MDM-AP status register- bit[10], "Standby mode exit". The debugger can read the status after it regains JTAG access to be sure that power gated mode was exited and not just any other reset.

The debugger is now able to reconfigure the desired debug state. Once done, it sets the Standby mode debug acknowledge (STANDBYDBGACK) – bit[6] in MDM-AP control register to let SRC to de-assert the core reset.

3. Inhibit Sleep: This is another way in which the debugger can handle the system standby modes. The inhibit Sleep is set using the configuration of MDM-AP control register. The debugger can set this bit, check if it is set (if yes the system has not gone into standby while the bit was being set) and then carry on with the debug accesses. Since inhibit sleep bit is set the system cannot move into standby and the debugger can continue with the accesses without risk of losing communication. Once the debugger is done it can reset the bit and allow the standby transitions (in case the system so desire). The same is repeated every time the debugger wants to make debug accesses.

   In case the system goes into standby while the inhibit Sleep was reset and the debugger now wants to make debug accesses, it initiates a write to SET inhibit Sleep and on read back does not get the expected response. Thus it knows that the system is in standby. The debugger can continue this until the device comes out of standby.

20.11 Secured JTAG

The SJC block offers a range of security levels. The SJC blocks the access to debug based on eFuse configuration and authentication. This is summarized in the table below:

S. No.	Name	Fuse used	Comments	Security Level	Flexibility to change the security level	Field Return
1	No Debug	JTAG_SMODE[1:0]	Closed for debug but allows basic JTAG features like IDCODE, BSR …	High	No change possible	The field return is supported using Fuse bit "FIELD_RETURN" This fuse is blown based on an authenticated image. The part which is received as field return is not returned to the customer. The field return part offers complete access to TCU and debug just like the in fab part.
2	Secured JTAG	JTAG_SMODE[1:0]	Authentication based on challenge-Response (C-R)	Medium	Can switch to no debug	

Table continues on the next page...

S. No.	Name	Fuse used	Comments	Security Level	Flexibility to change the security level	Field Return
3	JTAG enabled	JTAG_SMODE[1:0]	Open	No security	Can switch to secured JTAG or No Debug	Full support possible for field return.

20.11.1 Additional Authentication Interface

Authentication interface aims to restrict access to debug and trace functionality. This is done by controlling the ARM debug authentication signals. For more details please refer to CoreSight v1.0 Architecture Specification. These are listed below:

Control Signal name	Description	Controlled by
DBGEN	Invasive Debug Enable	SJC based on security authentication
NIDEN	Non invasive Debug Enable	SJC based on security authentication
SPIDEN	Secure invasive debug enable	control bit In SRC (can be SET by only s/w running in secure world)
SPNIDEN	Secure non-invasive debug enable	control bit In SRC (can be SET by only s/w running in secure world)

While in FAB or for field return all the controls are enabled to allow open access.

The SJC controls the DBGEN and NIDEN based on the security authentication and perceived security incident related to power up. This allows debugger access to non secure coresight components and allows non secure traces to be traced out.

In case debug in the secure world is required the SPIDEN and SPNIDEN needs to be set. This is feasible only by s/w running in the secure world. Refer to id-_Ref306981484 for details.

20.12 Configuration sequence

20.12.1 Halt mode

This section explains how the different debugger types can make accesses to the debug logic.

1. In case of 2 wire CJTAG debugger send the sequence over TMS and TCK to switch CJTAG in 2 wires (refer to JTAG-to-cJTAG change sequence)

   Else

   In case of ARM SWD debugger send the sequence to switch the DAP from JTAG to SWD (refer to JTAG-to-SWD change sequence)

   Else

   Continue with the IEEE 1149.1 4-wire interface.
2. Access ARM DAP Instruction registers.
3. Access "SJC" through JTAG AP.
4. Clear security authentication.
5. Continue with debug access.

20.12.2 Monitor mode

This is an application initiated mode where in debugger is not connected. In this mode the application writes to a bit in the CCM which allows to override CDBGPWRUPREQ and hence un gate the dap clock. In case of monitor mode only the CA5 debug IPs can be configured and used. We cannot use it for CM4 debug.

Chapter 21
Direct Memory Access Controller (eDMA)

21.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source- and destination-address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 32 channels

21.1.1 Block diagram

This diagram illustrates the eDMA module.

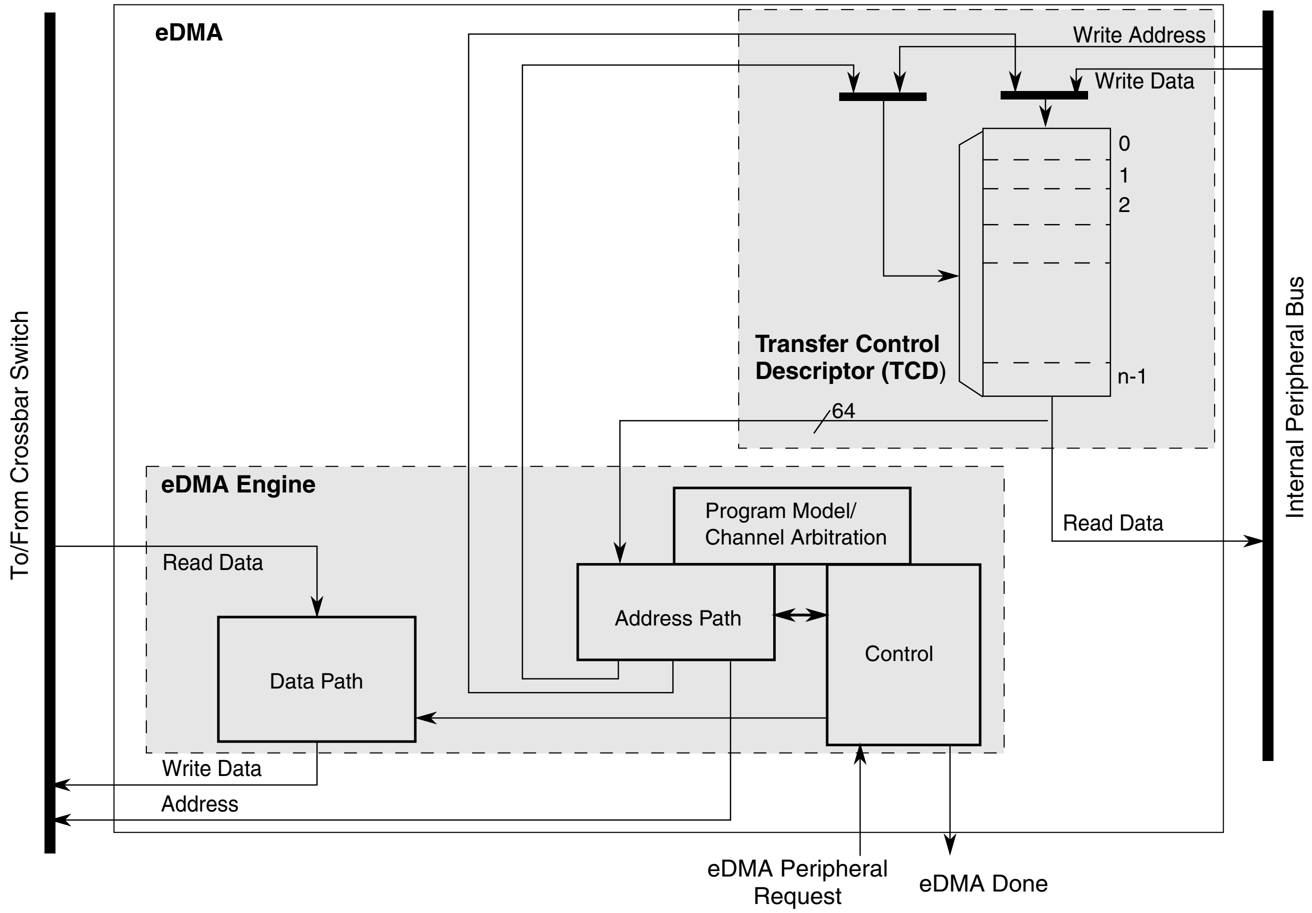


Figure 21-1. eDMA block diagram

21.1.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer-control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 21-1. eDMA engine submodules

Submodule	Function
Address path	This block implements registered versions of two channel transfer control descriptors, channel x and channel y, and manages all master bus-address calculations. All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by DCHPRI*n*[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution. When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD*n*_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCD*n*_CITER field, and a possible fetch of the next TCD*n* from memory as part of a scatter/gather operation.
Data path	This block implements the bus master read/write datapath. It includes 16 bytes of register storage and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output. The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the 1st stage of the bus pipeline (address phase), while the data path module implements the 2nd stage of the pipeline (data phase).
Program model/channel arbitration	This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
Control	This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write.

The transfer-control descriptor local memory is further partitioned into:

Table 21-2. Transfer control descriptor memory

Submodule	Description
Memory controller	This logic implements the required dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus. As noted earlier, in the event of simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
Memory array	TCD storage for each channel's transfer profile.

21.1.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize the required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and not defined within the data packet itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for enhanced addressing modes
- 32-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage to support 16- and 32-byte transfers
  - Connections to the crossbar switch for bus mastering the data movement
- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via optional interrupt requests
  - One interrupt per channel, optionally asserted at completion of major iteration count
  - Optional error terminations per channel and logically summed together to form one error interrupt to the interrupt controller
- Optional support for scatter/gather DMA processing

- Support for complex data structures
- Support to cancel transfers via software

In the discussion of this module, *n* is used to reference the channel number.

21.2 Modes of operation

The eDMA operates in the following modes:

Table 21-3. Modes of operation

Mode	Description
Normal	In Normal mode, the eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with the eDMA. A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the transfer control descriptor (TCD). The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.
Debug	DMA operation is configurable in Debug mode via the control register: • If CR[EDBG] is cleared, the DMA continues to operate. • If CR[EDBG] is set, the eDMA stops transferring data. If Debug mode is entered while a channel is active, the eDMA continues operation until the channel retires.
Wait	Before entering Wait mode, the DMA attempts to complete its current transfer. After the transfer completes, the device enters Wait mode.

21.3 Memory map/register definition

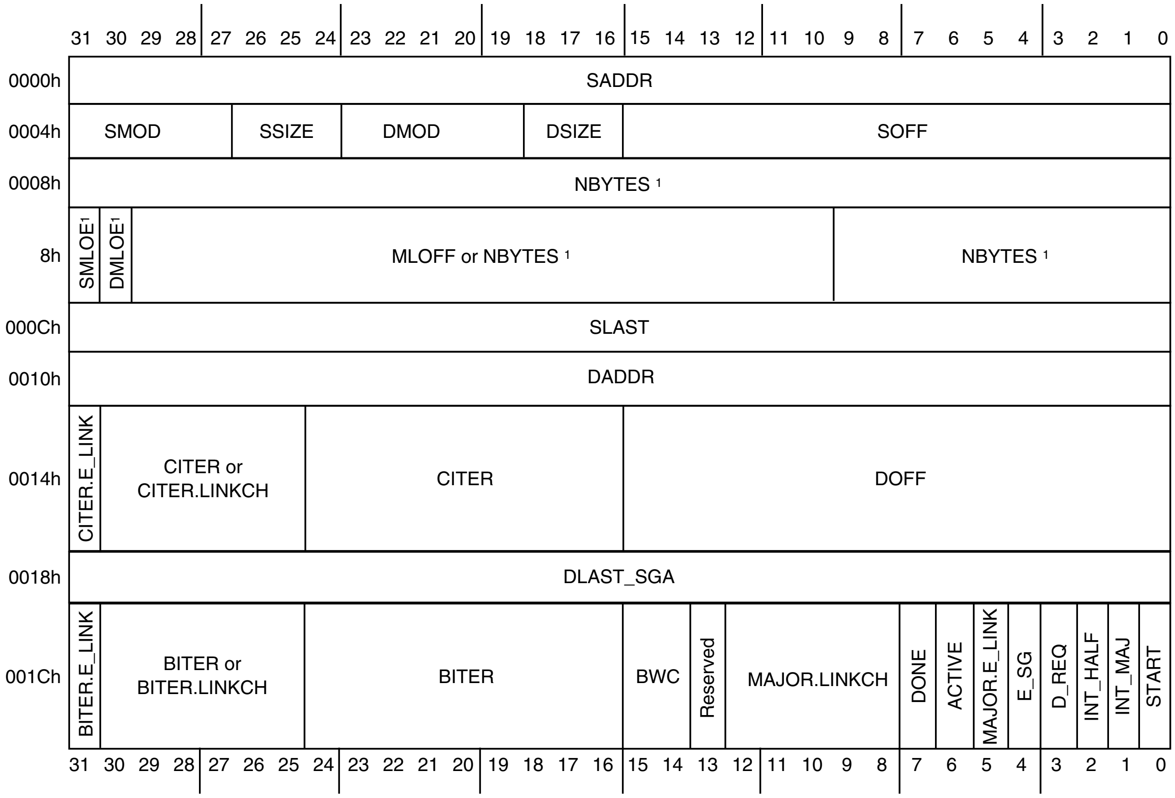
The eDMA's programming model is partitioned into two regions:

- The first region defines a number of registers providing control functions
- The second region corresponds to the local transfer control descriptor (TCD) memory

  Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0, channel 1,... channel 31. Each TCD*n* definition is presented as 11 registers of 16 or 32 bits.

  TCD Initialization: Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

Here is the TCD structure:



[1] The fields implemented in Word 2 depend on whether DMA_CR[EMLM] is 0 or 1.

Reserved memory and bit fields:

- Reading reserved bits in a register returns the value of zero.
- Writes to reserved bits in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

DMA memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4001_8000	Control Register (DMA0_CR)	32	R/W	0000_0400h	21.3.1/990

DMA memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4009_93FE	TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA1_TCD31_BITER_ELINKNO)	16	R/W	Undefined	21.3.32/ 1038

21.3.1 Control Register (DMAx_CR)

The CR defines the basic operating configuration of the DMA. The DMA arbitrates channel service requests in two groups of 16 channels each:

- Group 1 contains channels 31-16
- Group 0 contains channels 15-0

Arbitration within a group can be configured to use either a fixed-priority or a round-robin scheme. For fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The channel priority registers assign the priorities; see the DCHPRIn registers. For round-robin arbitration, the channel priorities are ignored and channels within each group are cycled through (from high to low channel number) without regard to priority.

NOTE

For proper operation, writes to the CR register must be performed only when the DMA channels are inactive; that is, when TCDn_CSR[ACTIVE] bits are cleared.

The group priorities operate in a similar fashion. In group fixed priority arbitration mode, channel service requests in the highest priority group are executed first, where priority level 1 is the highest and priority level 0 is the lowest. The group priorities are assigned in the GRPnPRI fields of the DMA Control Register (CR). All group priorities must have unique values prior to any channel service requests occurring; otherwise, a configuration error will be reported. For group round robin arbitration, the group priorities are ignored and the groups are cycled through (from high to low group number) without regard to priority.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. When minor loop offsets are enabled, the minor loop offset (MLOFF) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both prior to the addresses being written back into the TCD. If the major loop is

complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (EMLM is 1), TCDn word2 is redefined. A portion of TCDn word2 is used to specify multiple fields: a source enable bit (SMLOE) to specify the minor loop offset should be applied to the source address (TCDn_SADDR) upon minor loop completion, a destination enable bit (DMLOE) to specify the minor loop offset should be applied to the destination address (TCDn_DADDR) upon minor loop completion, and the sign extended minor loop offset value (MLOFF). The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. When both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

When minor loop mapping is disabled (EMLM is 0), all 32 bits of TCDn word2 are assigned to the NBYTES field.

Address: Base address + 0h offset

DMAx_CR field descriptions

Field	Description
31–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17 CX	Cancel Transfer 0 Normal operation 1 Cancel the remaining data transfer. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The CX bit clears itself after the cancel has been honored. This cancel retires the channel normally as if the minor loop was completed.
16 ECX	Error Cancel Transfer

Table continues on the next page...

DMAx_CR field descriptions (continued)

Field	Description
	0 Normal operation 1 Cancel the remaining data transfer in the same fashion as the CX bit. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The ECX bit clears itself after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition, thus updating the Error Status register (DMAx_ES) and generating an optional error interrupt.
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10 GRP1PRI	Channel Group 1 Priority Group 1 priority level when fixed priority group arbitration is enabled.
9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 GRP0PRI	Channel Group 0 Priority Group 0 priority level when fixed priority group arbitration is enabled.
7 EMLM	Enable Minor Loop Mapping 0 Disabled. TCDn.word2 is defined as a 32-bit NBYTES field. 1 Enabled. TCDn.word2 is redefined to include individual enable fields, an offset field, and the NBYTES field. The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field is reduced when either offset is enabled.
6 CLM	Continuous Link Mode 0 A minor loop channel link made to itself goes through channel arbitration before being activated again. 1 A minor loop channel link made to itself does not go through channel arbitration before being activated again. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop.
5 HALT	Halt DMA Operations 0 Normal operation 1 Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared.
4 HOE	Halt On Error 0 Normal operation 1 Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared.
3 ERGA	Enable Round Robin Group Arbitration 0 Fixed priority arbitration is used for selection among the groups. 1 Round robin arbitration is used for selection among the groups.
2 ERCA	Enable Round Robin Channel Arbitration 0 Fixed priority arbitration is used for channel selection within each group. 1 Round robin arbitration is used for channel selection within each group.

Table continues on the next page...

DMAx_CR field descriptions (continued)

Field	Description
1 EDBG	Enable Debug 0 When in debug mode, the DMA continues to operate. 1 When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the system exits debug mode or the EDBG bit is cleared.
0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

21.3.2 Error Status Register (DMAx_ES)

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- A configuration error, that is:
  - An illegal setting in the transfer-control descriptor, or
  - An illegal priority register setting in fixed-arbitration
- An error termination to a bus master read or write cycle

See the Error Reporting and Handling section for more details.

DMAx_ES field descriptions

Field	Description
31 VLD	Logical OR of all ERR status bits 0 No ERR bits are set 1 At least one ERR bit is set indicating a valid error exists that has not been cleared
30–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 ECX	Transfer Canceled

Table continues on the next page...

DMAx_ES field descriptions (continued)

Field	Description
	0 No canceled transfers 1 The last recorded entry was a canceled transfer by the error cancel transfer input
15 GPE	Group Priority Error 0 No group priority error 1 The last recorded error was a configuration error among the group priorities. All group priorities are not unique.
14 CPE	Channel Priority Error 0 No channel priority error 1 The last recorded error was a configuration error in the channel priorities within a group. Channel priorities within a group are not unique.
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error, excluding GPE and CPE errors, or last recorded error canceled transfer.
7 SAE	Source Address Error 0 No source address configuration error. 1 The last recorded error was a configuration error detected in the TCDn_SADDR field. TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE].
6 SOE	Source Offset Error 0 No source offset configuration error 1 The last recorded error was a configuration error detected in the TCDn_SOFF field. TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE].
5 DAE	Destination Address Error 0 No destination address configuration error 1 The last recorded error was a configuration error detected in the TCDn_DADDR field. TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE].
4 DOE	Destination Offset Error 0 No destination offset configuration error 1 The last recorded error was a configuration error detected in the TCDn_DOFF field. TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE].
3 NCE	NBYTES/CITER Configuration Error 0 No NBYTES/CITER configuration error 1 The last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields. • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE], or • TCDn_CITER[CITER] is equal to zero, or • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK]
2 SGE	Scatter/Gather Configuration Error

Table continues on the next page...

DMAx_ES field descriptions (continued)

Field	Description
	0 No scatter/gather configuration error 1 The last recorded error was a configuration error detected in the TCDn_DLASTSGA field. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. TCDn_DLASTSGA is not on a 32 byte boundary.
1 SBE	Source Bus Error 0 No source bus error 1 The last recorded error was a bus error on a source read
0 DBE	Destination Bus Error 0 No destination bus error 1 The last recorded error was a bus error on a destination write

21.3.3 Enable Request Register (DMAx_ERQ)

The ERQ register provides a bit map for the 32 implemented channels to enable the request signal for each channel. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ. The {S,C}ERQ registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to the ERQ.

DMA request input signals and this enable request flag must be asserted before a channel's hardware service request is accepted. The state of the DMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.

21.3.4 Enable Error Interrupt Register (DMAx_EEI)

The EEI register provides a bit map for the 32 channels to enable the error interrupt signal for each channel. The state of any given channel's error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI. The {S,C}EEI are provided so the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEI register.

The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

21.3.5 Clear Enable Error Interrupt Register (DMAx_CEEI)

The CEEI provides a simple memory-mapped mechanism to clear a given bit in the EEI to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be cleared. Setting the CAEE bit provides a global clear function, forcing the EEI contents to be cleared, disabling all DMA request inputs. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: Base address + 18h offset

Bit	7	6	5	4	3	2	1	0
Read	0	0		0				
Write	NOP	CAEE	0	CEEI				
Reset	0	0	0	0	0	0	0	0

DMAx_CEEI field descriptions

Field	Description
7 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
6 CAEE	Clear All Enable Error Interrupts 0 Clear only the EEI bit specified in the CEEI field 1 Clear all bits in EEI
5 Reserved	This field is reserved.
4–0 CEEI	Clear Enable Error Interrupt Clears the corresponding bit in EEI

21.3.6 Set Enable Error Interrupt Register (DMAx_SEEI)

The SEEI provides a simple memory-mapped mechanism to set a given bit in the EEI to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI to be set. Setting the SAEE bit provides a global set function, forcing the entire EEI contents to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: Base address + 19h offset

Bit	7	6	5	4	3	2	1	0
Read	0	0		0				
Write	NOP	SAEE	0	SEEI				
Reset	0	0	0	0	0	0	0	0

DMAx_SEEI field descriptions

Field	Description
7 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
6 SAEE	Sets All Enable Error Interrupts 0 Set only the EEI bit specified in the SEEI field. 1 Sets all bits in EEI
5 Reserved	This field is reserved.
4–0 SEEI	Set Enable Error Interrupt Sets the corresponding bit in EEI

21.3.7 Clear Enable Request Register (DMAx_CERQ)

The CERQ provides a simple memory-mapped mechanism to clear a given bit in the ERQ to disable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be cleared. Setting the CAER bit provides a global clear function, forcing the entire contents of the ERQ to be cleared, disabling all DMA request inputs. If NOP is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: Base address + 1Ah offset

Bit	7	6	5	4	3	2	1	0
Read	0	0		0				
Write	NOP	CAER	0	CERQ				
Reset	0	0	0	0	0	0	0	0

DMAx_CERQ field descriptions

Field	Description
7 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
6 CAER	Clear All Enable Requests 0 Clear only the ERQ bit specified in the CERQ field 1 Clear all bits in ERQ
5 Reserved	This field is reserved.
4–0 CERQ	Clear Enable Request Clears the corresponding bit in ERQ{H,L}

21.3.8 Set Enable Request Register (DMAx_SERQ)

The SERQ provides a simple memory-mapped mechanism to set a given bit in the ERQ to enable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ to be set. Setting the SAER bit provides a global set function, forcing the entire contents of ERQ to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: Base address + 1Bh offset

Bit	7	6	5	4	3	2	1	0
Read	0	0		0				
Write	NOP	SAER	0	SERQ				
Reset	0	0	0	0	0	0	0	0

DMAx_SERQ field descriptions

Field	Description
7 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
6 SAER	Set All Enable Requests 0 Set only the ERQ bit specified in the SERQ field 1 Set all bits in ERQ
5 Reserved	This field is reserved.
4–0 SERQ	Set Enable Request Sets the corresponding bit in ERQ

21.3.9 Clear DONE Status Bit Register (DMAx_CDNE)

The CDNE provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding transfer control descriptor to be cleared. Setting the CADN bit provides a global clear function, forcing all DONE bits to be cleared. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: Base address + 1Ch offset

Bit	7	6	5	4	3	2	1	0
Read	0	0		0				
Write	NOP	CADN	0	CDNE				
Reset	0	0	0	0	0	0	0	0

DMAx_CDNE field descriptions

Field	Description
7 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
6 CADN	Clears All DONE Bits 0 Clears only the TCDn_CSR[DONE] bit specified in the CDNE field 1 Clears all bits in TCDn_CSR[DONE]
5 Reserved	This field is reserved.
4–0 CDNE	Clear DONE Bit Clears the corresponding bit in TCDn_CSR[DONE]

21.3.10 Set START Bit Register (DMAx_SSRT)

The SSRT provides a simple memory-mapped mechanism to set the START bit in the TCD of the given channel. The data value on a register write causes the START bit in the corresponding transfer control descriptor to be set. Setting the SAST bit provides a global set function, forcing all START bits to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: Base address + 1Dh offset

Bit	7	6	5	4	3	2	1	0
Read	0	0		0				
Write	NOP	SAST	0	SSRT				
Reset	0	0	0	0	0	0	0	0

DMAx_SSRT field descriptions

Field	Description
7 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
6 SAST	Set All START Bits (activates all channels) 0 Set only the TCDn_CSR[START] bit specified in the SSRT field 1 Set all bits in TCDn_CSR[START]
5 Reserved	This field is reserved.
4–0 SSRT	Set START Bit Sets the corresponding bit in TCDn_CSR[START]

21.3.11 Clear Error Register (DMAx_CERR)

The CERR provides a simple memory-mapped mechanism to clear a given bit in the ERR to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the ERR to be cleared. Setting the CAEI bit provides a global clear function, forcing the ERR contents to be cleared, clearing all channel error indicators. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: Base address + 1Eh offset

Bit	7	6	5	4	3	2	1	0
Read	0	0		0				
Write	NOP	CAEI	0	CERR				
Reset	0	0	0	0	0	0	0	0

DMAx_CERR field descriptions

Field	Description
7 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
6 CAEI	Clear All Error Indicators 0 Clear only the ERR bit specified in the CERR field 1 Clear all bits in ERR
5 Reserved	This field is reserved.
4–0 CERR	Clear Error Indicator Clears the corresponding bit in ERR

21.3.12 Clear Interrupt Request Register (DMAx_CINT)

The CINT provides a simple, memory-mapped mechanism to clear a given bit in the INT to disable the interrupt request for a given channel. The given value on a register write causes the corresponding bit in the INT to be cleared. Setting the CAIR bit provides a global clear function, forcing the entire contents of the INT to be cleared, disabling all DMA interrupt requests. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Address: Base address + 1Fh offset

Bit	7	6	5	4	3	2	1	0
Read	0	0		0				
Write	NOP	CAIR	0	CINT				
Reset	0	0	0	0	0	0	0	0

DMAx_CINT field descriptions

Field	Description
7 NOP	No Op enable 0 Normal operation 1 No operation, ignore the other bits in this register
6 CAIR	Clear All Interrupt Requests 0 Clear only the INT bit specified in the CINT field 1 Clear all bits in INT
5 Reserved	This field is reserved.
4–0 CINT	Clear interrupt request Clears the corresponding bit in INT

21.3.13 Interrupt Request Register (DMAx_INT)

The INT register provides a bit map for the 32 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt on data transfer completion. The outputs of this register are directly routed to the interrupt controller (INTC). During the interrupt-service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT register in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT register. On writes to INT, a 1 in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no affect on the corresponding channel's current interrupt status. The CINT register is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT register.

21.3.14 Error Register (DMAx_ERR)

The ERR provides a bit map for the 32 channels, signaling the presence of an error for each channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI, then logically summed across groups of 16 and 32 channels to form several group error interrupt requests, which are then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. Typically, a write to the CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected.

The contents of this register can also be polled because a non-zero value indicates the presence of a channel error regardless of the state of the EEI. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a one in any bit position clears the corresponding channel's error status. A zero in any bit position has no affect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be cleared.

21.3.15 Hardware Request Status Register (DMAx_HRS)

The HRS register provides a bit map for the DMA channels, signaling the presence of a hardware request for each channel. The hardware request status bits reflect the current state of the register and qualified (via the ERQ fields) DMA request signals as seen by the DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

NOTE

These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQ bits.

21.3.17 Channel n Priority Register (DMA*x*_DCHPRI*n*)

When fixed-priority channel arbitration is enabled (CR[ERCA] = 0), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, etc. Software must program the channel priorities with unique values; otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15. When read, the GRPPRI bits of the DCHPRIn register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not affected by writes to the DCHPRIn registers. The group priority is assigned in the DMA control register.

Address: Base address + 100h offset + (1d × i), where i=0d to 31d

Bit	7	6	5	4	3	2	1	0
Read	ECP	DPA	GRPPRI		CHPRI			
Write								
Reset	0	0	*	*	*	*	*	*

* Notes:
- GRPPRI field: See bit field description
- CHPRI field: See bit field description

DMA*x*_DCHPRI*n* field descriptions

Field	Description
7 ECP	Enable Channel Preemption. This bit resets to zero. 0 Channel n cannot be suspended by a higher priority channel's service request 1 Channel n can be temporarily suspended by the service request of a higher priority channel
6 DPA	Disable preempt ability. This bit resets to zero. 0 Channel n can suspend a lower priority channel 1 Channel n cannot suspend any channel, regardless of channel priority
5–4 GRPPRI	Channel n Current Group Priority Group priority assigned to this channel group when fixed-priority arbitration is enabled. These two bits are read only; writes are ignored. **NOTE:** Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, i.e., DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] equals 0b1111.
3–0 CHPRI	Channel n Arbitration Priority Channel priority when fixed-priority arbitration is enabled

Table continues on the next page...

DMAx_DCHPRIn field descriptions (continued)

Field	Description
	NOTE: Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, i.e., DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] equals 0b01111.

DMAx_TCDn_ATTR field descriptions

Field	Description
15–11 SMOD	Source Address Modulo 0 Source address modulo feature is disabled ≠0 This value defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range.
10–8 SSIZE	Source data transfer size Using a reserved encoding causes a configuration error. 000 8-bit 001 16-bit 010 32-bit 011 64-bit 100 Reserved 101 32-byte 110 Reserved 111 Reserved
7–3 DMOD	Destination Address Modulo See the SMOD definition
2–0 DSIZE	Destination Data Transfer Size See the SSIZE definition

21.3.21 TCD Minor Byte Count (Minor Loop Disabled) (DMAx_TCD*n*_NBYTES_MLNO)

This register, or one of the next two registers (TCD_NBYTES_MLOFFNO, TCD_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is disabled (CR[EMLM] = 0)

If minor loop mapping is enabled, see the TCD_NBYTES_MLOFFNO and TCD_NBYTES_MLOFFYES register descriptions for TCD word 2's definition.

Address: Base address + 1008h offset + (32d × i), where i=0d to 31d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

* Notes:

- x = Undefined at reset.

DMAx_TCD*n*_NBYTES_MLNO field descriptions

Field	Description
31–0 NBYTES	Minor Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. (Although, it may be stalled by using the bandwidth control field, or via preemption.) After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. **NOTE:** An NBYTES value of 0x0000_0000 is interpreted as a 4 GB transfer.

21.3.22 TCD Signed Minor Loop Offset (Minor Loop Enabled and Offset Disabled) (DMAx_TCD*n*_NBYTES_MLOFFNO)

One of three registers (this register, TCD_NBYTES_MLNO, or TCD_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- SMLOE = 0 and DMLOE = 0

If minor loop mapping is enabled and SMLOE or DMLOE is set, then refer to the TCD_NBYTES_MLOFFYES register description. If minor loop mapping is disabled, then refer to the TCD_NBYTES_MLNO register description.

Address: Base address + 1008h offset + (32d × i), where i=0d to 31d

DMAx_TCDn_NBYTES_MLOFFNO field descriptions

Field	Description
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 The minor loop offset is not applied to the SADDR 1 The minor loop offset is applied to the SADDR
30 DMLOE	Destination Minor Loop Offset enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 The minor loop offset is not applied to the DADDR 1 The minor loop offset is applied to the DADDR
29–0 NBYTES_OE	Minor Byte Transfer Count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. (Although, it may be stalled by using the bandwidth control field, or via preemption.) After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

21.3.23 TCD Signed Minor Loop Offset (Minor Loop and Offset Enabled) (DMA*x*_TCD*n*_NBYTES_MLOFFYES)

One of three registers (this register, TCD_NBYTES_MLNO, or TCD_NBYTES_MLOFFNO), defines the number of bytes to transfer per request. Which register to use depends on whether minor loop mapping is disabled, enabled but not used for this channel, or enabled and used.

TCD word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- Minor loop offset is enabled (SMLOE or DMLOE = 1)

If minor loop mapping is enabled and SMLOE and DMLOE are cleared, then refer to the TCD_NBYTES_MLOFFNO register description. If minor loop mapping is disabled, then refer to the TCD_NBYTES_MLNO register description.

Address: Base address + 1008h offset + (32d × i), where i=0d to 31d

* Notes:
- x = Undefined at reset.

DMAx_TCDn_CITER_ELINKYES field descriptions

Field	Description
15 ELINK	Enable channel-to-channel linking on minor-loop complete As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** This bit must be equal to the BITER[ELINK] bit; otherwise, a configuration error is reported. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
14 Reserved	This field is reserved.
13–9 LINKCH	Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by these five bits by setting that channel's TCDn_CSR[START] bit.
8–0 CITER_LE	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations (e.g., final source and destination address calculations), optionally generating an interrupt to signal channel completion before reloading the CITER field from the beginning iteration count (BITER) field. **NOTE:** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE:** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

21.3.28 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMAx_TCDn_CITER_ELINKNO)

If TCDn_CITER[ELINK] is cleared, the TCDn_CITER register is defined as follows.

Address: Base address + 1016h offset + (32d × i), where i=0d to 31d

Bit	15	14	13	12	11	10	9	8
Read Write	ELINK	CITER

Reset	x*	x*	x*	x*	x*	x*	x*	x*

* Notes:
- x = Undefined at reset.

DMAx_TCDn_CITER_ELINKNO field descriptions

Field	Description
15 ELINK	Enable channel-to-channel linking on minor-loop complete As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** This bit must be equal to the BITER[ELINK] bit; otherwise, a configuration error is reported. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
14–0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations (e.g., final source and destination address calculations), optionally generating an interrupt to signal channel completion before reloading the CITER field from the beginning iteration count (BITER) field. **NOTE:** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE:** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

21.3.29 TCD Last Destination Address Adjustment/Scatter Gather Address (DMAx_TCDn_DLASTSGA)

Address: Base address + 1018h offset + (32d × i), where i=0d to 31d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

* Notes:
- x = Undefined at reset.

DMAx_TCDn_DLASTSGA field descriptions

Field	Description
31–0 DLASTSGA	Destination last address adjustment or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0), then: • Adjustment value added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo-32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo-32-byte, else a configuration error is reported.

21.3.30 TCD Control and Status (DMAx_TCDn_CSR)

Address: Base address + 101Ch offset + (32d × i), where i=0d to 31d

Bit	15	14	13	12	11	10	9	8

Reset	x*	x*	x*	x*	x*	x*	x*	x*

* Notes:
- x = Undefined at reset.

DMA*x*_TCD*n*_CSR field descriptions

Field	Description
15–14 BWC	Bandwidth Control Throttles the amount of bus bandwidth consumed by the eDMA. In general, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch. **NOTE:** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00 No eDMA engine stalls 01 Reserved 10 eDMA engine stalls for 4 cycles after each r/w 11 eDMA engine stalls for 8 cycles after each r/w
13 Reserved	This field is reserved.

12–8
MAJORLINKCH
	Link Channel Number
	
	If (MAJORELINK = 0) then
	• No channel-to-channel linking (or chaining) is performed after the major loop counter is exhausted.
	
	else
	
	• After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by these five bits by setting that channel's TCDn_CSR[START] bit.

7 DONE	Channel Done This flag indicates the eDMA has completed the major loop. The eDMA engine sets it as the CITER count reaches zero; The software clears it, or the hardware when the channel is activated. **NOTE:** This bit must be cleared to write the MAJORELINK or ESG bits. This bit resets to zero.
6 ACTIVE	Channel Active This flag signals the channel is currently in execution. It is set when channel service begins, and the eDMA clears it as the minor loop completes or if any error condition is detected.
5 MAJORELINK	Enable channel-to-channel linking on major loop complete As the channel completes the major loop, this flag enables the linking to another channel, defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. **NOTE:** To support the dynamic linking coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
4 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLASTSGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as the transfer control descriptor into the local memory.

Table continues on the next page...

DMAx_TCDn_CSR field descriptions (continued)

Field	Description
	NOTE: To support the dynamic scatter/gather coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set. 0 The current channel's TCD is normal format. 1 The current channel's TCD specifies a scatter gather format. The DLASTSGA field provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution.
3 DREQ	Disable Request If this flag is set, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches zero. 0 The channel's ERQ bit is not affected 1 The channel's ERQ bit is cleared when the major loop is complete
2 INTHALF	Enable an interrupt when major counter is half complete. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT register when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER >> 1)). This halfway point interrupt request is provided to support double-buffered (aka ping-pong) schemes or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE:** If BITER is set, do not use INTHALF. Use INTMAJOR instead. 0 The half-point interrupt is disabled 1 The half-point interrupt is enabled
1 INTMAJOR	Enable an interrupt when major iteration count completes If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches zero. 0 The end-of-major loop interrupt is disabled 1 The end-of-major loop interrupt is enabled
0 START	Channel Start If this flag is set, the channel is requesting service. The eDMA hardware automatically clears this flag after the channel begins execution. This bit resets to zero. 0 The channel is not explicitly started 1 The channel is explicitly started via a software initiated service request

21.3.31 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA*x*_TCD*n*_BITER_ELINKYES)

If the TCDn_BITER[ELINK] bit is set, the TCDn_BITER register is defined as follows.

Address: Base address + 101Eh offset + (32d × i), where i=0d to 31d

Bit	15	14	13	12	11	10	9	8
Read / Write	ELINK	0 (Write)	LINKCH					BITER_LE
Reset	x*	x*	x*	x*	x*	x*	x*	x*

Reset	x*	x*	x*	x*	x*	x*	x*	x*

* Notes:
- x = Undefined at reset.

DMA*x*_TCD*n*_BITER_ELINKYES field descriptions

Field	Description
15 ELINK	Enables channel-to-channel linking on minor loop complete As the channel completes the minor loop, this flag enables the linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
14 Reserved	This field is reserved.
13–9 LINKCH	Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by these six bits by setting that channel's TCDn_CSR[START] bit. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field.
8–0 BITER_LE	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field.

Table continues on the next page...

DMAx_TCDn_BITER_ELINKYES field descriptions (continued)

Field	Description
	NOTE: When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

21.3.32 TCD Beginning Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMAx_TCDn_BITER_ELINKNO)

If the TCDn_BITER[ELINK] bit is cleared, the TCDn_BITER register is defined as follows.

Address: Base address + 101Eh offset + (32d × i), where i=0d to 31d

Bit	15	14	13	12	11	10	9	8

* Notes:
- x = Undefined at reset.

DMAx_TCDn_BITER_ELINKNO field descriptions

Field	Description
15 ELINK	Enables channel-to-channel linking on minor loop complete As the channel completes the minor loop, this flag enables the linking to another channel, defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE:** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field. 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
14–0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. As the major iteration count is exhausted, the contents of this field are reloaded into the CITER field.

Table continues on the next page...

DMAx_TCDn_BITER_ELINKNO field descriptions (continued)

Field	Description
	NOTE: When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, the contents of this field is reloaded into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

21.4 Functional description

21.4.1 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

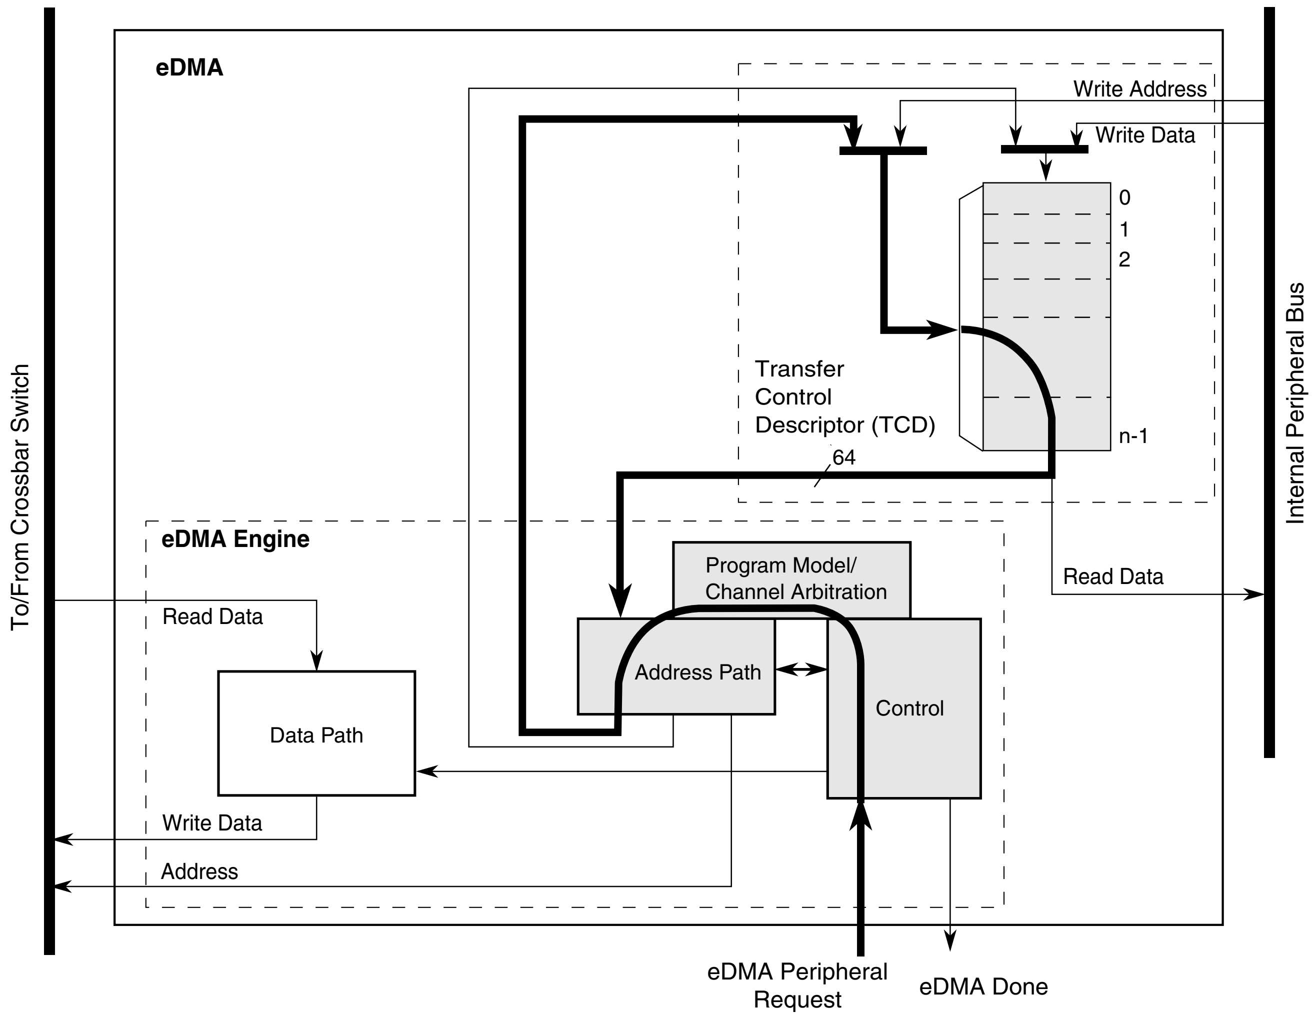

Figure 21-1634. eDMA operation, part 1

This example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, the channel arbitration performs, using the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the required descriptor read from the local memory and loaded into the eDMA engine address path channel x or y registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path channel x or y registers.

The following diagram illustrates the second part of the basic data flow:

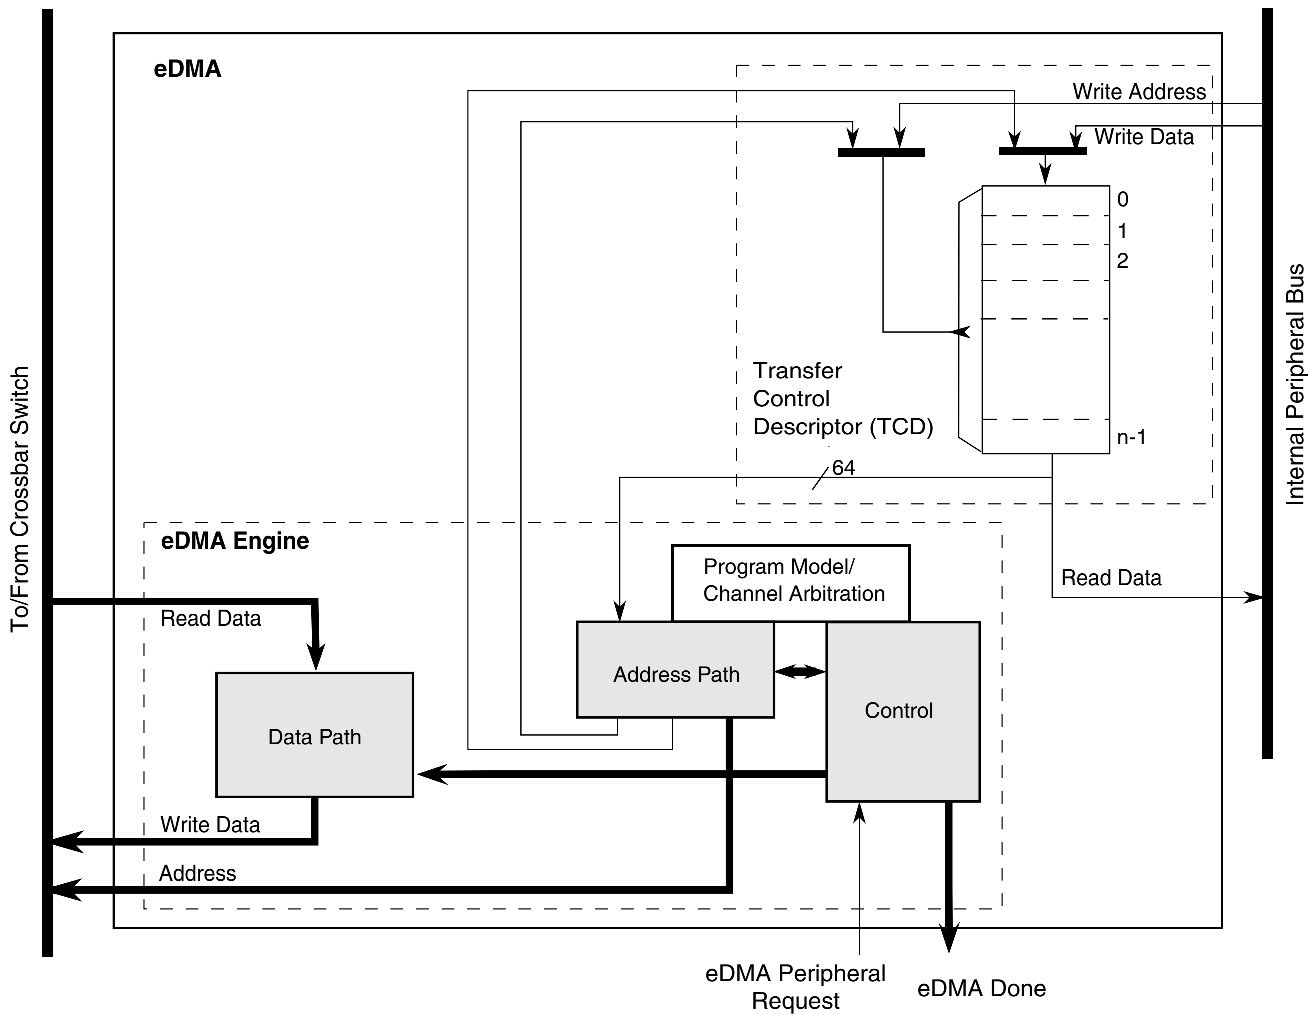

Figure 21-1635. eDMA operation, part 2

The modules associated with the data transfer (address path, data path, and control) sequence through the required source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD, e.g., SADDR, DADDR, CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

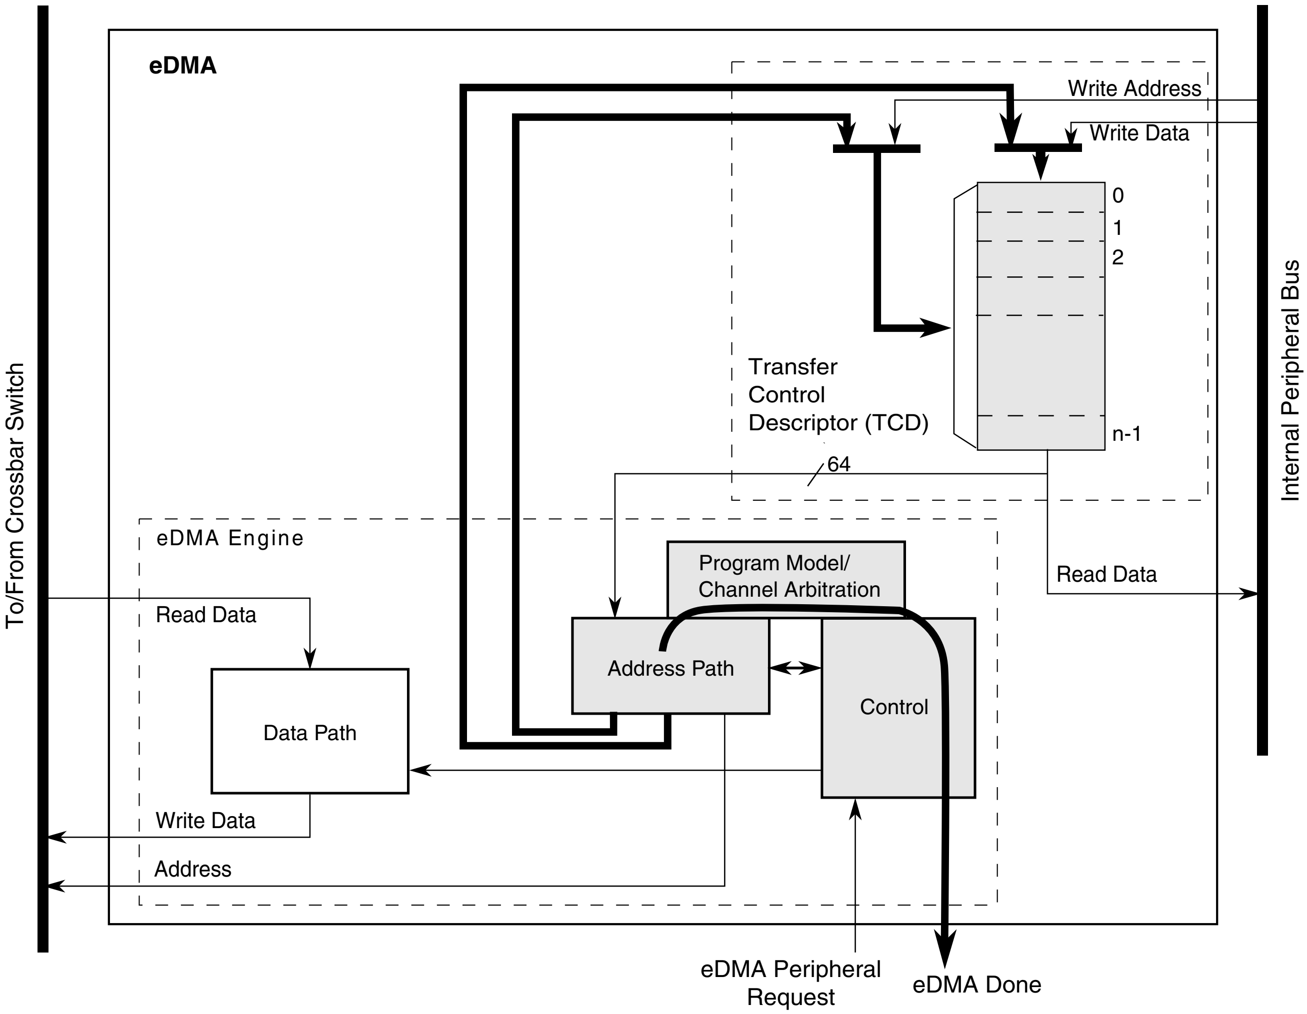

Figure 21-1636. eDMA operation, part 3

21.4.2 Error reporting and handling

Channel errors are reported in the Error Status register (DMAx_ES) and can be caused by:

- A configuration error, which is an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed-Arbitration mode, or
- An error termination to a bus master read or write cycle

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes are detailed below:

- The addresses and offsets must be aligned on 0-modulo-transfer-size boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size respectively.
- In fixed arbitration mode, a configuration error is caused by any two channel priorities being equal. All channel priority levels must be unique when fixed arbitration mode is enabled.
- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[E_LINK] bit does not equal the TCDn_BITER[E_LINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the

data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

A transfer may be cancelled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the Error Status register (DMAx_ES) is updated with the cancelled channel number and ECX is set. The TCD of a cancelled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD because the aforementioned fields no longer represent the original parameters. When a transfer is cancelled by the error cancel transfer mechanism, the channel number is loaded into DMA_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has peipeline effect), and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the Error Status register (DMAx_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

21.4.3 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the DCHPRIn[ECP] bit. Channel preemption allows the executing channel’s data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel has completed all its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected.

A channel's ability to preempt another channel can be disabled by setting DCHPRIn[DPA]. When a channel's preempt ability is disabled, that channel cannot suspend a lower priority channel's data transfer, regardless of the lower priority channel's ECP setting. This allows for a pool of low priority, large data-moving channels to be defined. These low priority channels can be configured to not preempt each other, thus preventing a low priority channel from consuming the preempt slot normally available to a true, high priority channel.

21.4.4 Performance

This section addresses the performance of the eDMA module, focusing on two separate metrics:

- In the traditional data movement context, performance is best expressed as the peak data transfer rates achieved using the eDMA. In most implementations, this transfer rate is limited by the speed of the source and destination address spaces.
- In a second context where device-paced movement of single data values to/from peripherals is dominant, a measure of the requests that can be serviced in a fixed time is a more relevant metric. In this environment, the speed of the source and destination address spaces remains important. However, the microarchitecture of the eDMA also factors significantly into the resulting metric.

21.4.4.1 Peak transfer rates

The peak transfer rates for several different source and destination transfers are shown in the following tables. These tables assume:

- Internal SRAM can be accessed with zero wait-states when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states, when viewed from the system bus data phase
- All internal peripheral bus accesses are 32-bits in size

This table compares peak transfer rates based n different possible system speeds. Specific chips/devices may not support all system speeds listed.

Table 21-1639. eDMA peak transfer rates (Mbytes/sec)

System Speed, Width	Internal SRAM-to-Internal SRAM	32b internal peripheral bus-to-Internal SRAM	Internal SRAM-to-32b internal peripheral bus
66.7 MHz, 64b	266.7	66.6	53.3
83.3 MHz, 64b	333.3	83.3	66.7
100.0 MHz, 64b	400.0	100.0	80.0
133.3 MHz, 64b	533.3	133.3	106.7
150.0 MHz, 64b	600.0	150.0	120.0

Internal-SRAM-to-internal-SRAM transfers occur at the core's datapath width. For all transfers involving the internal peripheral bus, 32-bit transfer sizes are used. In all cases, the transfer rate includes the time to read the source plus the time to write the destination.

21.4.4.2 Peak request rates

The second performance metric is a measure of the number of DMA requests that can be serviced in a given amount of time. For this metric, assume that the peripheral request causes the channel to move a single internal peripheral bus-mapped operand to/from internal SRAM. The same timing assumptions used in the previous example apply to this calculation. In particular, this metric also reflects the time required to activate the channel.

The eDMA design supports the following hardware service request sequence. Note that the exact timing from Cycle 7 is a function of the response times for the channel's read and write accesses. In the case of an internal peripheral bus read and internal SRAM write, the combined data phase time is 4 cycles. For an SRAM read and internal peripheral bus write, it is 5 cycles.

Table 21-1640. Hardware service request process

Cycle		Description
With internal peripheral bus read and internal SRAM write	With SRAM read and internal peripheral bus write	
1		eDMA peripheral request is asserted.
2		The eDMA peripheral request is registered locally in the eDMA module and qualified. TCD*n*_CSR[START] bit initiated requests start at this point with the registering of the user write to TCD*n* word 7.
3		Channel arbitration begins.
4		Channel arbitration completes. The transfer control descriptor local memory read is initiated.

Table continues on the next page...

Table 21-1640. Hardware service request process (continued)

Cycle		Description
With internal peripheral bus read and internal SRAM write	With SRAM read and internal peripheral bus write	
5–6		The first two parts of the activated channel's TCD is read from the local memory. The memory width to the eDMA engine is 64 bits, so the entire descriptor can be accessed in four cycles
7		The first system bus read cycle is initiated, as the third part of the channel's TCD is read from the local memory. Depending on the state of the crossbar switch, arbitration at the system bus may insert an additional cycle of delay here.
8–11	8–12	The last part of the TCD is read in. This cycle represents the first data phase for the read, and the address phase for the destination write.
12	13	This cycle represents the data phase of the last destination write.
13	14	The eDMA engine completes the execution of the inner minor loop and prepares to write back the required TCD*n* fields into the local memory. The TCD*n* word 7 is read and checked for channel linking or scatter/gather requests.
14	15	The appropriate fields in the first part of the TCD*n* are written back into the local memory.
15	16	The fields in the second part of the TCD*n* are written back into the local memory. This cycle coincides with the next channel arbitration cycle start.
16	17	The next channel to be activated performs the read of the first part of its TCD from the local memory. This is equivalent to Cycle 4 for the first channel's service request.

Assuming zero wait states on the system bus, DMA requests can be processed every 9 cycles. Assuming an average of the access times associated with internal peripheral bus-to-SRAM (4 cycles) and SRAM-to-internal peripheral bus (5 cycles), DMA requests can be processed every 11.5 cycles (4 + (4+5)/2 + 3). This is the time from Cycle 4 to Cycle x +5. The resulting peak request rate, as a function of the system frequency, is shown in the following table.

Table 21-1641. eDMA peak request rate (MReq/sec)

System frequency (MHz)	Request rate with zero wait states	Request rate with wait states
66.6	7.4	5.8
83.3	9.2	7.2
100.0	11.1	8.7
133.3	14.8	11.6
150.0	16.6	13.0

A general formula to compute the peak request rate with overlapping requests is:

PEAKreq = freq / [entry + (1 + read_ws) + (1 + write_ws) + exit]

where:

Table 21-1642. Peak request formula operands

Operand	Description
PEAKreq	Peak request rate
freq	System frequency
entry	Channel startup (4 cycles)
read_ws	Wait states seen during the system bus read data phase
write_ws	Wait states seen during the system bus write data phase
exit	Channel shutdown (3 cycles)

21.4.4.3 eDMA performance example

Consider a system with the following characteristics:

- Internal SRAM can be accessed with one wait-state when viewed from the system bus data phase
- All internal peripheral bus reads require two wait-states, and internal peripheral bus writes three wait-states viewed from the system bus data phase
- System operates at 150 MHz

For an SRAM to internal peripheral bus transfer,

PEAKreq = 150 MHz / [4 + (1 + 1) + (1 + 3) + 3] cycles = 11.5 Mreq/sec

For an internal peripheral bus to SRAM transfer,

PEAKreq = 150 MHz / [4 + (1 + 2) + (1 + 1) + 3] cycles = 12.5 Mreq/sec

Assuming an even distribution of the two transfer types, the average peak request rate would be:

PEAKreq = (11.5 Mreq/sec + 12.5 Mreq/sec) / 2 = 12.0 Mreq/sec

The minimum number of cycles to perform a single read/write, zero wait states on the system bus, from a cold start where no channel is executing and eDMA is idle are:

- 11 cycles for a software, that is, a TCD*n*_CSR[START] bit, request
- 12 cycles for a hardware, that is, an eDMA peripheral request signal, request

Two cycles account for the arbitration pipeline and one extra cycle on the hardware request resulting from the internal registering of the eDMA peripheral request signals. For the peak request rate calculations above, the arbitration and request registering is absorbed in or overlaps the previous executing channel.

Note

When channel linking or scatter/gather is enabled, a two cycle delay is imposed on the next channel selection and startup. This allows the link channel or the scatter/gather channel to be eligible and considered in the arbitration pool for next channel selection.

21.5 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

21.5.1 eDMA initialization

To initialize the eDMA:

1. Write to the CR if a configuration other than the default is desired.
2. Write the channel priority levels to the DCHPRI*n* registers if a configuration other than the default is desired.
3. Enable error interrupts in the EEI register if so desired.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the ERQ register.
6. Request channel service via either:
   - Software: setting the TCD*n*_CSR[START]
   - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in the following table, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, as defined by TCD*n*_SADDR, to the destination, as defined by TCD*n*_DADDR, continue until the number of bytes specified by TCD*n*_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing executes, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 21-1643. TCD Control and Status fields

TCD*n*_CSR field name	Description
START	Control bit to start channel explicitly when using a software initiated DMA service (Automatically cleared by hardware)
ACTIVE	Status bit indicating the channel is currently in execution
DONE	Status bit indicating major loop completion (cleared by software when using a software initiated DMA service)
D_REQ	Control bit to disable DMA request at end of major loop completion when using a hardware initiated DMA service
BWC	Control bits for throttling bandwidth control of a channel
E_SG	Control bit to enable scatter-gather feature
INT_HALF	Control bit to enable interrupt when major loop is half complete
INT_MAJ	Control bit to enable interrupt when major loop completes

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

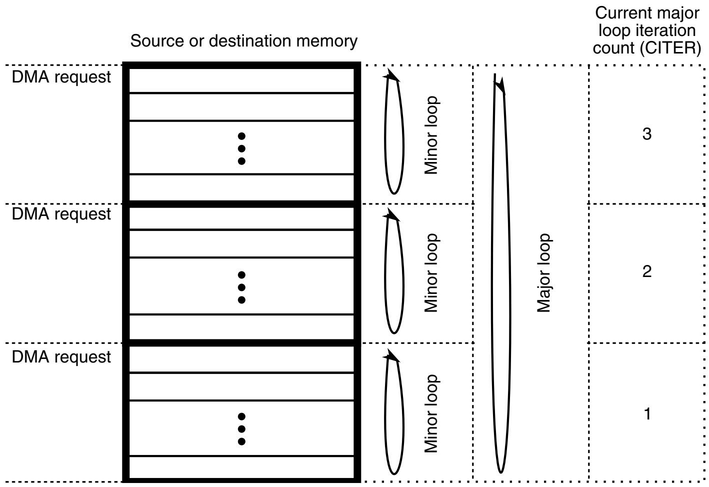

Figure 21-1637. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings interrelate.

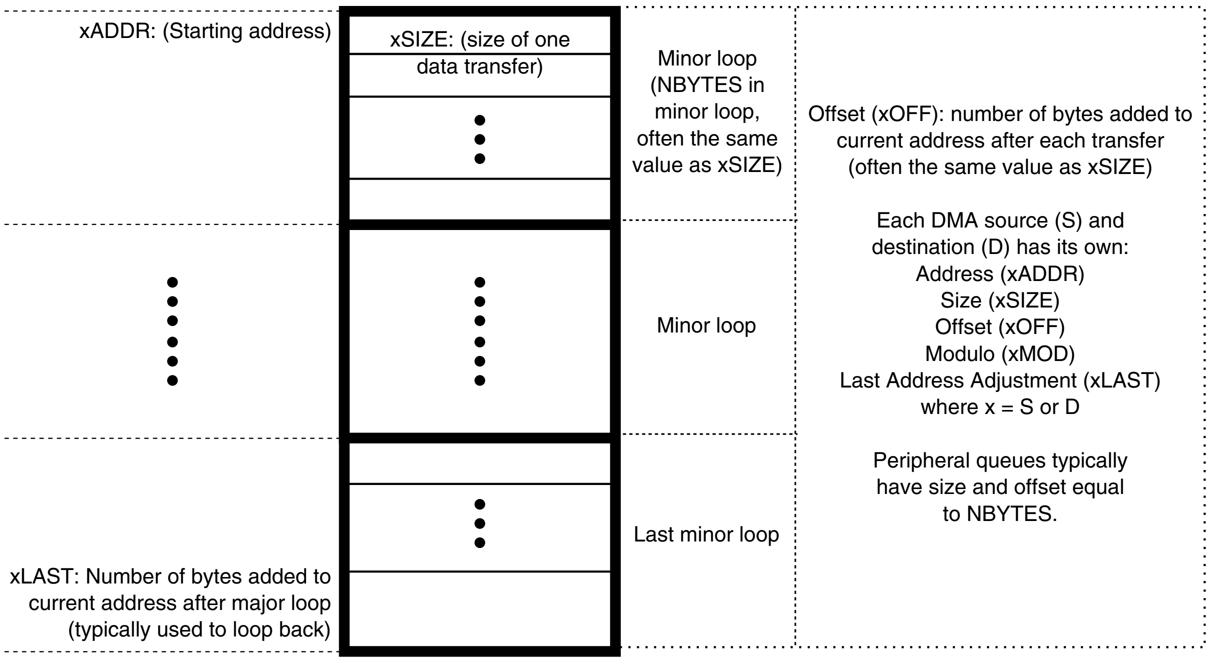

Figure 21-1638. Memory array terms

21.5.2 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per channel basis with the exception of channel priority error (ES[CPE]).

For all error types other than group or channel priority errors, the channel number causing the error is recorded in the Error Status register (DMAx_ES). If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

Channel priority errors are identified within a group once that group has been selected as the active group. For example:

1. The eDMA is configured for fixed group and fixed channel arbitration modes.
2. Group 1 is the highest priority and all channels are unique in that group.
3. Group 0 is the next highest priority and has two channels with the same priority level.
4. If Group 1 has any service requests, those requests will be executed.
5. After all of Group 1 requests have completed, Group 0 will be the next active group.
6. If Group 0 has a service request, then an undefined channel in Group 0 will be selected and a channel priority error will occur.
7. This repeats until the all of Group 0 requests have been removed or a higher priority Group 1 request comes in.

In this sequence, for item 2, the eDMA acknowledge lines will assert only if the selected channel is requesting service via the eDMA peripheral request signal. If interrupts are enabled for all channels, the user will get an error interrupt, but the channel number for the ERR register and the error interrupt request line may be wrong because they reflect the selected channel. A group priority error is global and any request in any group will cause a group priority error.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest channel/group priority with an active request is selected, but the lowest numbered channel with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting is associated with the selected channel.

21.5.3 Arbitration mode considerations

21.5.3.1 Fixed group arbitration, Fixed channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so that the channels within one group use "fixed" priorities, and that group is assigned the highest "fixed" priority of all groups, that group can take all the bandwidth of the eDMA controller. That is, no other groups will be serviced if there is always at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly. Preemption is available in this scenario only.

21.5.3.2 Fixed group arbitration, Round-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This scenario could cause the same bandwidth consumption problem as indicated in Fixed group arbitration, Fixed channel arbitration, but all the channels in the highest priority group will be serviced. Service latency will be short on the highest priority group, but could potentially be very much longer as the group priority decreases.

21.5.4 Performing DMA transfers (examples)

21.5.4.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the TCD*n*_CSR[DONE] bit is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are

programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA= -16
TCDn_CSR[INT_MAJ] = 1
TCDn_CSR[START] = 1 (Should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] bit requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
    a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
    b. Write 32-bits to location 0x2000 → first iteration of the minor loop.
    c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
    d. Write 32-bits to location 0x2004 → second iteration of the minor loop.
    e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
    f. Write 32-bits to location 0x2008 → third iteration of the minor loop.
    g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
    h. Write 32-bits to location 0x200C → last iteration of the minor loop → major loop complete.

6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[*n*] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

21.5.4.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware, that is, eDMA peripheral, request for channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source to destination transfers are executed as follows:
    a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
    b. Write 32-bits to location 0x2000 → first iteration of the minor loop.
    c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
    d. Write 32-bits to location 0x2004 → second iteration of the minor loop.
    e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
    f. Write 32-bits to location 0x2008 → third iteration of the minor loop.

    g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
    h. Write 32-bits to location 0x200C → last iteration of the minor loop.
6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0.
8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware, that is, eDMA peripheral, requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: TCD*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, TCD*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads: channel TCD data from local memory to internal register file.
13. The source to destination transfers are executed as follows:
    a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
    b. Write 32-bits to location 0x2010 → first iteration of the minor loop.
    c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
    d. Write 32-bits to location 0x2014 → second iteration of the minor loop.
    e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
    f. Write 32-bits to location 0x2018 → third iteration of the minor loop.
    g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
    h. Write 32-bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2 (TCD*n*_BITER).
15. eDMA engine writes: TCD*n*_CSR[ACTIVE] = 0, TCD*n*_CSR[DONE] = 1, INT[n] = 1.

16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

21.5.4.3 Using the modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567*x*) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes and the MOD field is set to 4, allowing for a 2^4 byte (16-byte) size queue.

Table 21-1644. Modulo example

Transfer Number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670

21.5.5 Monitoring transfer descriptor status

21.5.5.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software initiated service requests. The first is to read the TCD*n*_CITER field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test the TCD*n*_CSR[START] bit and the TCD*n*_CSR[ACTIVE] bit. The minor-loop-complete condition is indicated by both bits reading zero after the TCD*n*_CSR[START] was set. Polling the TCD*n*_CSR[ACTIVE] bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute the following sequence for a software activated channel:

Stage	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	1	0	0	Channel service request via software
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

The best method to test for minor-loop completion when using hardware, that is, peripheral, initiated service requests is to read the TCD*n*_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute the following sequence for a hardware-activated channel:

Stage	TCD*n*_CSR bits			State
	START	ACTIVE	DONE	
1	0	0	0	Channel service request via hardware (peripheral request asserted)
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

For both activation types, the major-loop-complete status is explicitly indicated via the TCD*n*_CSR[DONE] bit.

The TCD*n*_CSR[START] bit is cleared automatically when the channel begins execution regardless of how the channel activates.

21.5.5.2 Reading the transfer descriptors of active channels

The eDMA reads back the true TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_NBYTES values if read while a channel executes. The true values of the SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses, SADDR and DADDR, and NBYTES, which decrement to zero as the transfer progresses, can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

21.5.5.3 Checking channel preemption status

Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in fixed group, fixed channel arbitration mode, the determination of the actively running relative priority outstanding requests become undefined. Channel and/or group priorities are treated as equal, that is, constantly rotating, when Round-Robin Arbitration mode is selected.

The TCD*n*_CSR[ACTIVE] bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two TCD*n*_CSR[ACTIVE] bits are set simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

21.5.6 Channel Linking

Channel linking (or chaining) is a mechanism where one channel sets the TCD*n*_CSR[START] bit of another channel (or itself), therefore initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCD*n*_CITER[E_LINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[E_LINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_E_LINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] bit
2. Minor loop done → set TCD12_CSR[START] bit
3. Minor loop done → set TCD12_CSR[START] bit
4. Minor loop done, major loop done→ set TCD7_CSR[START] bit

When minor loop linking is enabled (TCD*n*_CITER[E_LINK] = 1), the TCD*n*_CITER[CITER] field uses a nine bit vector to form the current iteration count. When minor loop linking is disabled (TCD*n*_CITER[E_LINK] = 0), the TCD*n*_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCD*n*_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

Note

The TCD*n*_CITER[E_LINK] bit and the TCD*n*_BITER[E_LINK] bit must equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, i.e, use another channel's TCD, at the end of a loop.

Table 21-1645. Channel Linking Parameters

Desired Link Behavior	TCD Control Field Name	Description
Link at end of Minor Loop	CITER[E_LINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	CITER[LINKCH]	Link channel number when linking at end of minor loop (current iteration)
Link at end of Major Loop	CSR[MAJOR_E_LINK]	Enable channel-to-channel linking on major loop completion
	CSR[MAJOR_LINKCH]	Link channel number when linking at end of major loop

21.5.7 Dynamic programming

21.5.7.1 Dynamically changing the channel priority

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to Round-Robin Channel Arbitration mode, change the channel priorities, then switch back to Fixed Arbitration mode,
2. Disable all the channels, change the channel priorities, then enable the appropriate channels.

21.5.7.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCD.major.e_link bit during channel execution. This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCD.major.e_link bit at the same time the eDMA engine is retiring the channel. The TCD.major.e_link would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The following coherency model is recommended when executing a dynamic channel link request.

1. Write 1 to the TCD.major.e_link bit.
2. Read back the TCD.major.e_link bit.
3. Test the TCD.major.e_link request status:
    - If TCD.major.e_link = 1, the dynamic link attempt was successful.
    - If TCD.major.e_link = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCD.major.e_link bit to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

NOTE

The user must clear the TCD.done bit before writing the TCD.major.e_link bit. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

21.5.7.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources.When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in eDMA programmer's model, thus replacing the current descriptor.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic scatter/gather operation by enabling the TCD.e_sg bit at the same time the eDMA engine

is retiring the channel. The TCD.e_sg would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the major.linkch field and the e_sg bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD.major.e_link and TCD.e_sg bits to zero on any writes to a channel's TCD.word7 if that channel's TCD.done bit is set indicating the major loop is complete.

NOTE

The user must clear the TCD.done bit before writing the TCD.major.e_link or TCD.e_sg bits. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.

21.5.7.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCD.major.e_link bit is zero, the TCD.major.linkch field is not used by the eDMA. In this case, the TCD.major.linkch bits may be used for other purposes. This method uses the TCD.major.linkch field as a TCD indentification (ID).

1. When the descriptors are built, write a unique TCD ID in the TCD.major.linkch field for each TCD associated with a channel using dynamic scatter/gather.
2. Write 1b to the TCD.d_req bit.

   Should a dynamic scatter/gather attempt fail, setting the TCD.d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offest value.

3. Write the TCD.dlast_sga field with the scatter/gather address.
4. Write 1b to the TCD.e_sg bit.
5. Read back the 16 bit TCD control/status field.
6. Test the TCD.e_sg request status and TCD.major.linkch value:

   If e_sg = 1b, the dynamic link attempt was successful.

If e_sg = 0b and the major.linkch (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring).

If e_sg = 0b and the major.linkch (ID) changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

21.5.7.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCD.dlast_sga field as a TCD indentification (ID).

1. Write 1b to the TCD.d_req bit.

   Should a dynamic scatter/gather attempt fail, setting the d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offest value.

2. Write theTCD.dlast_sga field with the scatter/gather address.
3. Write 1b to the TCD.e_sg bit.
4. Read back the TCD.e_sg bit.
5. Test the TCD.e_sg request status:

   If e_sg = 1b, the dynamic link attempt was successful.

   If e_sg = 0b, read the 32 bit TCD dlast_sga field.

   If e_sg = 0b and the dlast_sga did not change, the attempted dynamic link did not succeed (the channel was already retiring).

   If e_sg = 0b and the dlast_sga changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

Chapter 22
Direct Memory Access Multiplexer (DMAMUX)

22.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

22.1.1 Overview

The direct memory access multiplexer (DMAMUX) routes DMA sources, called slots, to any of the 16 DMA channels. This process is illustrated in the following figure.

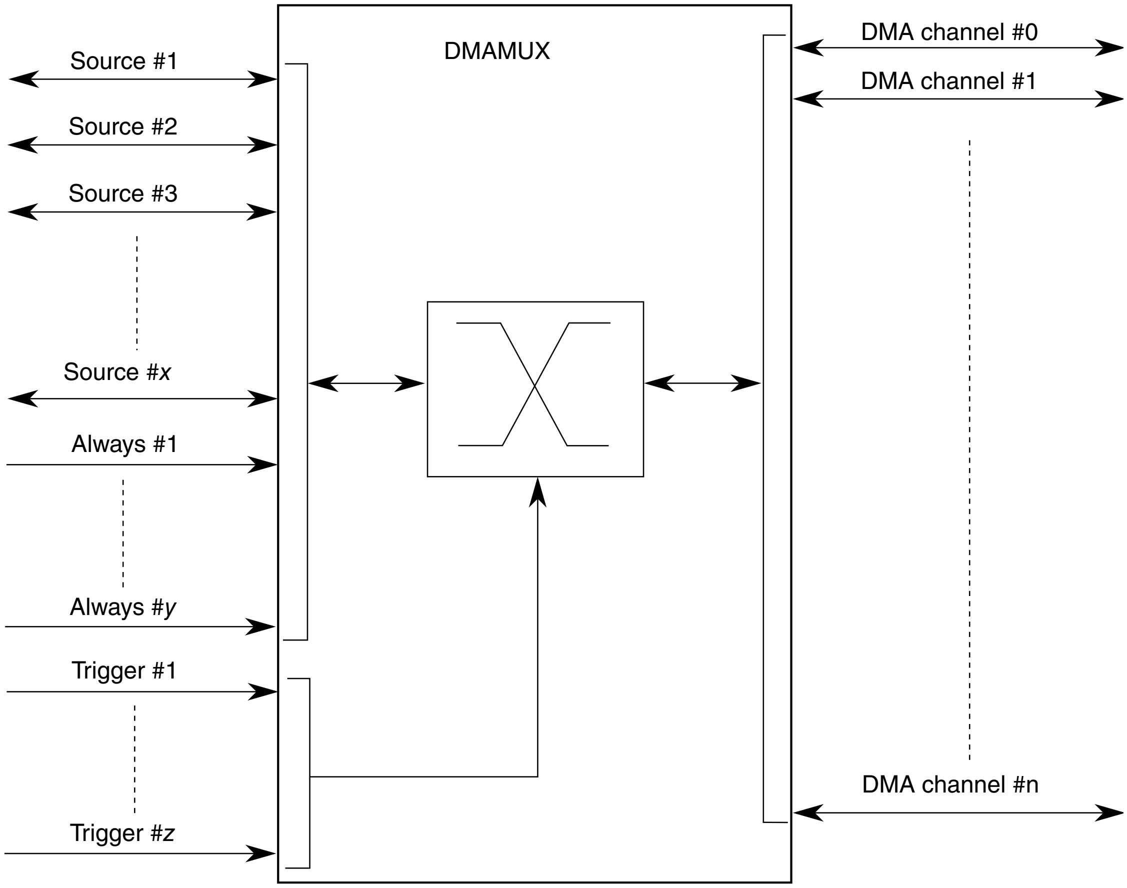

Figure 22-1. DMAMUX block diagram

22.1.2 Features

The DMAMUX module provides these features:

- Up to 53 peripheral slots and up to 10 always-on slots can be routed to 16 channels.
- 16 independently selectable DMA channel routers.
    - The first four channels additionally provide a trigger functionality.
- Each channel router can be assigned to one of the possible peripheral DMA slots or to one of the always-on slots.

22.1.3 Modes of operation

The following operating modes are available:

- Disabled mode

In this mode, the DMA channel is disabled. Because disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA channel MUX. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place, for example, changing the period of a DMA trigger.

- Normal mode

  In this mode, a DMA source is routed directly to the specified DMA channel. The operation of the DMAMUX in this mode is completely transparent to the system.

- Periodic Trigger mode

  In this mode, a DMA source may only request a DMA transfer, such as when a transmit buffer becomes empty or a receive buffer becomes full, periodically. Configuration of the period is done in the registers of the periodic interrupt timer (PIT). This mode is available only for channels 0–3.

22.2 External signal description

The DMAMUX has no external pins.

22.3 Memory map/register definition

This section provides a detailed description of all memory-mapped registers in the DMAMUX.

DMAMUX memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

22.3.1 Channel Configuration register (DMAMUXx_CHCFGn)

Each of the DMA channels can be independently enabled/disabled and associated with one of the DMA slots (peripheral slots or always-on slots) in the system.

NOTE

Setting multiple CHCFG registers with the same source value will result in unpredictable behavior.

Before changing the trigger or source settings, a DMA channel must be disabled via the CHCFGn[ENBL] bit.

Address: Base address + 0h offset + (1d × i), where i=0d to 15d

Reset	0	0	0	0	0	0	0	0

DMAMUXx_CHCFGn field descriptions

Field	Description
7 ENBL	DMA Channel Enable Enables the DMA channel. 0 DMA channel is disabled. This mode is primarily used during configuration of the DMAMux. The DMA has separate channel enables/disables, which should be used to disable or reconfigure a DMA channel. 1 DMA channel is enabled
6 TRIG	DMA Channel Trigger Enable Enables the periodic trigger capability for the triggered DMA channel. 0 Triggering is disabled. If triggering is disabled and the ENBL bit is set, the DMA Channel will simply route the specified source to the DMA channel. (Normal mode) 1 Triggering is enabled. If triggering is enabled and the ENBL bit is set, the DMAMUX is in Periodic Trigger mode.
5–0 SOURCE	DMA Channel Source (Slot) Specifies which DMA source, if any, is routed to a particular DMA channel. See your device's chip configuration details for information about the peripherals and their slot numbers.

22.4 Functional description

The primary purpose of the DMAMUX is to provide flexibility in the system's use of the available DMA channels. As such, configuration of the DMAMUX is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in Enabling and configuring sources is followed, the configuration of the DMAMUX may be changed during the normal operation of the system.

Functionally, the DMAMUX channels may be divided into two classes:

- Channels that implement the normal routing functionality plus periodic triggering capability
- Channels that implement only the normal routing functionality

22.4.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first 4 channels of the DMAMUX provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames, or packets at fixed intervals without the need for processor intervention. The trigger is generated by the periodic interrupt timer (PIT); as such, the configuration of the periodic triggering interval is done via configuration registers in the PIT. See the section on periodic interrupt timer for more information on this topic.

Note

Because of the dynamic nature of the system (due to DMA channel priorities, bus arbitration, interrupt service routine lengths, etc.), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

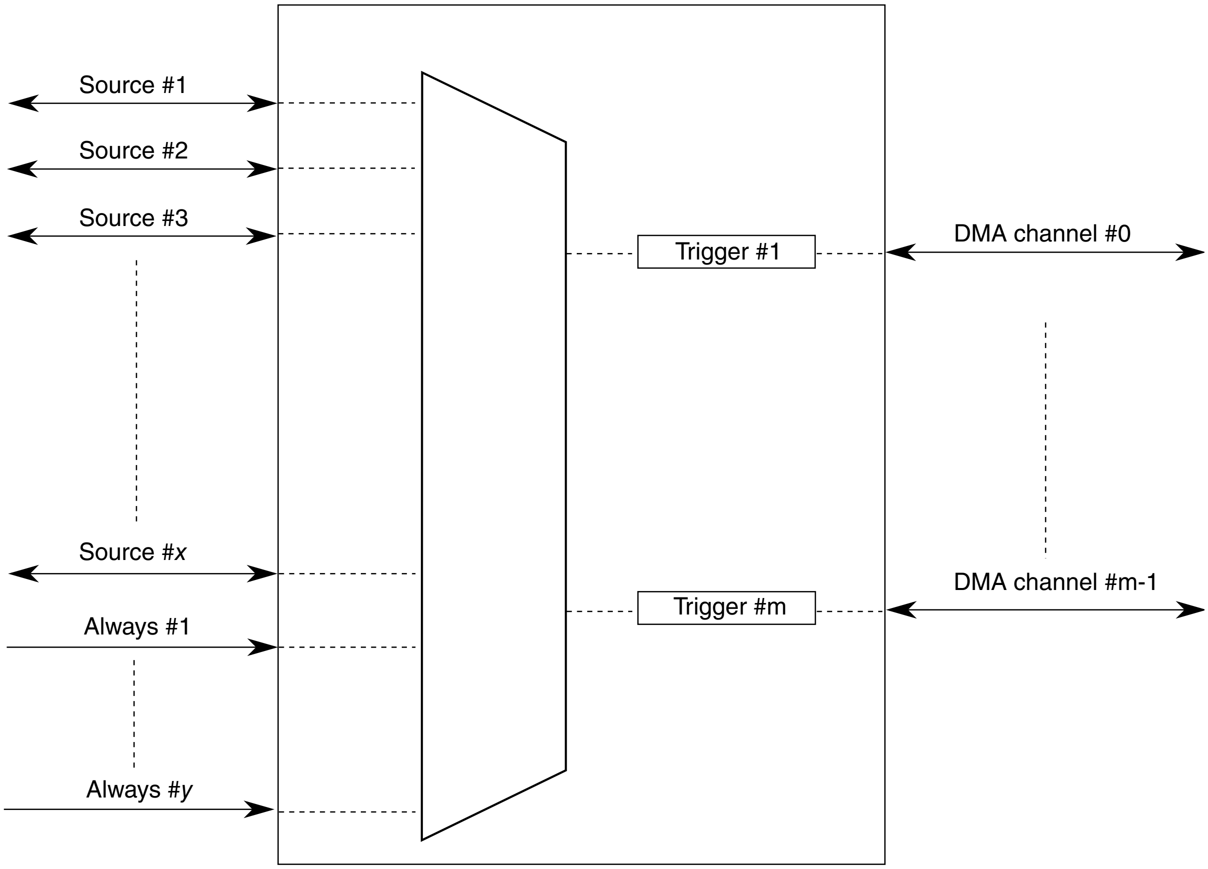

Figure 22-87. DMAMUX triggered channels

The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the peripheral to the DMA until a trigger event has been seen. This is illustrated in the following figure.

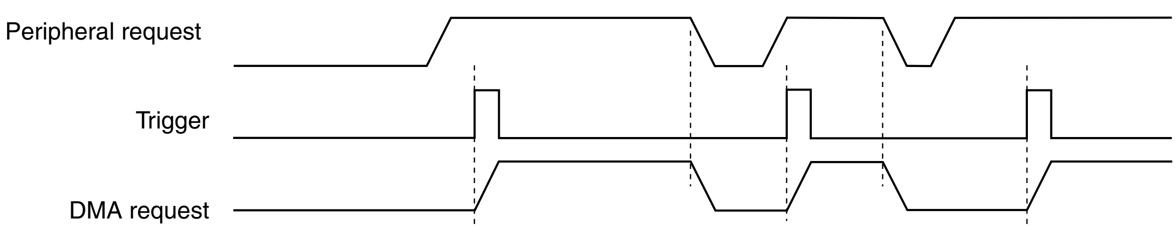

Figure 22-88. DMAMUX channel triggering: normal operation

After the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral reasserts its request and the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, then that trigger will be ignored. This situation is illustrated in the following figure.

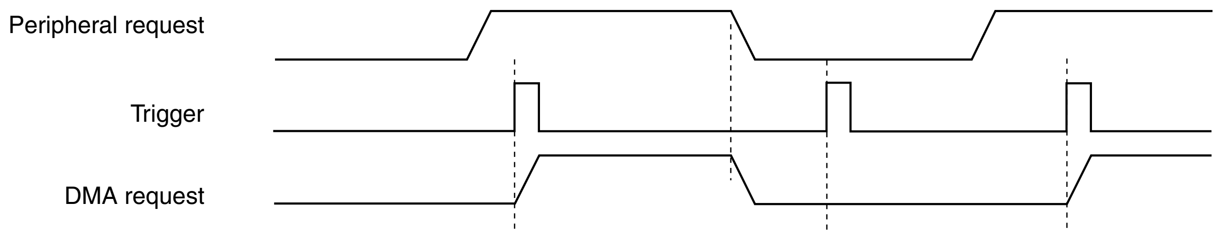

Figure 22-89. DMAMUX channel triggering: ignored trigger

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations:

- Periodically polling external devices on a particular bus

  As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. After it has been set up, the SPI will request DMA transfers, presumably from memory, as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5 μs (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.

- Using the GPIO ports to drive or sample waveforms

  By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

A more detailed description of the capability of each trigger, including resolution, range of values, and so on, may be found in the periodic interrupt timer section.

22.4.2 DMA channels with no triggering capability

The other channels of the DMAMUX provide the normal routing functionality as described in Modes of operation.

22.4.3 Always-enabled DMA sources

In addition to the peripherals that can be used as DMA sources, there are 10 additional DMA sources that are always enabled. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the sources that are always enabled provide no such "throttling" of the data transfers. These sources are most useful in the following cases:

- Performing DMA transfers to/from GPIO—Moving data from/to one or more GPIO pins, either unthrottled (that is, as fast as possible), or periodically (using the DMA triggering capability).
- Performing DMA transfers from memory to memory—Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Performing DMA transfers from memory to the external bus, or vice-versa—Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation—Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, an always-enabled DMA source can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require that a new start event be sent. This can either be a new software activation, or a transfer request from the DMA channel MUX. The options for doing this are:

- Transfer all data in a single minor loop.

  By configuring the DMA to transfer all of the data in a single minor loop (that is, major loop counter = 1), no reactivation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will impose on the system. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use explicit software reactivation.

  In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to reactivate the channel by writing to the DMA registers *after every minor loop*. For this option, the DMA channel must be disabled in the DMA channel MUX.

- Use an always-enabled DMA source.

In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMA channel MUX does the channel reactivation. For this option, the DMA channel should be enabled and pointing to an "always enabled" source. Note that the reactivation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

22.5 Initialization/application information

This section provides instructions for initializing the DMA channel MUX.

22.5.1 Reset

The reset state of each individual bit is shown in Memory map/register definition. In summary, after reset, all channels are disabled and must be explicitly enabled before use.

22.5.2 Enabling and configuring sources

To enable a source with periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Configure the corresponding timer.
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with periodic triggering capability:

1. Write 0x00 to CHCFG1 (base address + 0x01).

2. Configure channel 1 in the DMA, including enabling the channel.
3. Configure a timer for the desired trigger interval.
4. Write 0xC5 to CHCFG1 (base address + 0x01).

The following code example illustrates steps 1 and 4 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0xFC084000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCONFIG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCONFIG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCONFIG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCONFIG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCONFIG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCONFIG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCONFIG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCONFIG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCONFIG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCONFIG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCONFIG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCONFIG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCONFIG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCONFIG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCONFIG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCONFIG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);

In File main.c:
#include "registers.h"
:
:
*CHCONFIG1 = 0x00;
*CHCONFIG1 = 0xC5;
```

To enable a source without periodic triggering:

1. Determine with which DMA channel the source will be associated. Note that only the first 4 DMA channels have periodic triggering capability.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] fields of the DMA channel.
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point.
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that CHCFG[ENBL] is set while CHCFG[TRIG] is cleared.

NOTE

The following is an example. See the chip configuration details for the number of this device's DMA channels that have triggering capability.

To configure source #5 transmit for use with DMA channel 1, with no periodic triggering capability:

1. Write 0x00 to CHCFG1 (base address + 0x01).
2. Configure channel 1 in the DMA, including enabling the channel.
3. Write 0x85 to CHCFG1 (base address + 0x01).

The following code example illustrates steps 1 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0xFC084000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCONFIG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCONFIG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCONFIG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCONFIG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCONFIG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCONFIG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCONFIG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCONFIG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCONFIG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCONFIG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCONFIG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCONFIG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCONFIG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCONFIG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCONFIG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCONFIG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);

In File main.c:
#include "registers.h"
:
:
*CHCONFIG1 = 0x00;
*CHCONFIG1 = 0x85;
```

To disable a source:

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCFG registers. Additionally, some module-specific configuration may be necessary. See the appropriate section for more details.

To switch the source of a DMA channel:

1. Disable the DMA channel in the DMA and reconfigure the channel for the new source.
2. Clear the CHCFG[ENBL] and CHCFG[TRIG] bits of the DMA channel.
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCFG register, ensuring that the CHCFG[ENBL] and CHCFG[TRIG] fields are set.

To switch DMA channel 8 from source #5 transmit to source #7 transmit:

1. In the DMA configuration registers, disable DMA channel 8 and reconfigure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn't have triggering capability.
2. Write 0x00 to CHCFG8 (base address + 0x08).
3. Write 0x87 to CHCFG8 (base address + 0x08). (In this example, setting CHCFG[TRIG] would have no effect due to the assumption that channel 8 does not support the periodic triggering functionality).

The following code example illustrates steps 2 and 3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR     0xFC084000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCONFIG0 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCONFIG1 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCONFIG2 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCONFIG3 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCONFIG4 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCONFIG5 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCONFIG6 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCONFIG7 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCONFIG8 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCONFIG9 = (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCONFIG10= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCONFIG11= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCONFIG12= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCONFIG13= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCONFIG14= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCONFIG15= (volatile unsigned char *) (DMAMUX_BASE_ADDR+0x000F);

In File main.c:
#include "registers.h"
:
:
*CHCONFIG8 = 0x00;
*CHCONFIG8 = 0x87;
```

Chapter 23
Peripheral Bridge (AIPS-Lite)

23.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The peripheral bridge converts the crossbar switch interface to an interface that can access most of the slave peripherals on this chip.

The peripheral bridge occupies 64 MB of the address space, which is divided into peripheral slots of . (It might be possible that all the peripheral slots are not used. See Memory map for details on slot assignments.) The bridge includes separate clock enable inputs for each of the slots to accommodate slower peripherals.

23.1.1 Features

Key features of the peripheral bridge are:

- Supports peripheral slots with 8-, 16-, and 32-bit datapath width
- Supports a pair of 32-bit transactions for selected 64-bit memory accesses

23.1.2 General operation

The slave devices connected to the peripheral bridge are modules which contain a programming model of control and status registers. The system masters read and write these registers through the peripheral bridge. The peripheral bridge performs a bus protocol conversion of the master transactions and generates the following as inputs to the peripherals:

- Module enables
- Module addresses
- Transfer attributes
- Byte enables
- Write data

The peripheral bridge selects and captures read data from the peripheral interface and returns it to the crossbar switch.

Each peripheral is allocated one or more block(s) of the memory map. Two global external module enables are available for the remaining address space to allow for customization and expansion of addressed peripheral devices.

The AIPS-Lite module uses the data width of accessed peripheral to perform proper data byte lane routing; no bus decomposition (bus sizing) is performed.

23.2 Functional description

The peripheral bridge functions as a bus protocol translator between the crossbar switch and the slave peripheral bus. Support is provided for generating a pair of 32-bit slave accesses when performing certain 64-bit peripheral accesses.

The peripheral bridge manages all transactions destined for the attached slave devices and generates select signals for modules on the peripheral bus by decoding accesses within the attached address space.

23.2.1 Access support

Aligned and misaligned 32-bit, 16-bit, and byte accesses are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the slave peripheral bus. Peripheral registers must not be misaligned, although no explicit checking is performed by the peripheral bridge. The peripheral bridge performs two slave peripheral bus transfers for allowed 64-bit transactions, to 32-bit sized peripheral slots only.All other accesses are performed with a single transfer.

All accesses to the peripheral slots must be sized less than or equal to the designated peripheral slot size. If an access is attempted that is larger than the targeted port, an error response is generated.

Chapter 24
IPS_Semaphores

24.1 Introduction

The module provides the hardware support needed in multi-core systems for implementing semaphores and provide a simple mechanism to achieve "lock/unlock" operations via a single write access. This approach eliminates architecture-specific implementations like atomic (indivisible) read-modify-write instructions or reservation mechanisms. The result is an architecture-neutral solution that provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

24.1.1 Multi-Core Programming 101: Software Gates

Multi-processor systems require a function that can be used to safely and easily provide a locking mechanism which is then used by system software to control access to shared data structures, shared hardware resources, etc. These "gating" mechanisms are used by the software to serialize (and synchronize) writes to shared data and/or resources to prevent race conditions and preserve memory coherency between different processes and processors.

Consider the following description of a typical use-case. Processor X enters a section of code where shared data values are to be updated. It must first acquire a semaphore; this can be considered "locking (or closing) a software gate." Once the gate has been locked, a properly-architected software system does not allow other processes (or processors) to execute the same code segment or modify the shared data structure protected by the gate, that is, other processes/processors are locked out. Many software implementations include a *spin-wait loop* within the lock function until the locking of the gate is accomplished. Once the lock has been obtained, Processor X continues execution and updates the data values protected by the particular lock. Once the updates are complete, Processor X unlocks (or opens) the software gate, allowing other processes/processors access to the updated data values.

There are three important rules that must be followed for a correctly-implemented system solution:

1. All writes to shared data values or shared hardware resources must be protected by a "gate" variable.
2. Once a processor locks a gate, accesses to the shared data or resources by other processes/processors must be blocked. This is enforced by software conventions.
3. The processor that locks a particular gate is the only processor that can open (unlock) that gate.

Information in the hardware gate identifying the locking processor can be extremely useful for system-level debugging.

The Hennessy/Patterson text on computer architecture offers the following description of software gating.

"One of the major requirements of a shared-memory architecture multiprocessor is being able to coordinate processes that are working on a common task. Typically, a programmer will use *lock variables* to synchronize the processes.

The difficulty for the architect of a multiprocessor is to provide a mechanism to decide which processor gets the lock and to provide the operation that locks a variable. Arbitration is easy for shared-bus multiprocessors, since the bus is the only path to memory. The processor that gets the bus locks out all the other processors from memory. If the CPU and bus provide an atomic swap operation, programmers can create locks with the proper semantics. The adjective *atomic* is key, for it means that a processor can both read a location **and** set it to the locked value in the same bus operation, preventing any other processor from reading or writing memory." [Hennessy/Patterson, *Computer Architecture: A Quantitative Approach*, ppg. 471-472]

The classic text continues with a description of the steps required to lock/unlock a variable using an *atomic swap instruction*.

"Assume that 0 means unlocked and 1 means locked. A processor first reads the lock variable to test its state. A processor keeps reading and testing until the value indicates that the lock is unlocked. The processor then races against all other processes that were similarly "spin waiting" to see who can lock the variable first. All processes use a swap instruction that reads the old value and stores a 1 into the lock variable. The single winner will see the 0, and the losers will see a 1 that was placed there by the winner. (The losers will continue to set the variable to the locked value, but that doesn't matter.) The winning processor executes the code after the lock and then stores a 0 into the lock when it exits,

starting the race all over again. Testing the old value and then setting to a new value is why the atomic swap instruction is called *test and set* in some instruction sets." [Hennessy/Patterson, *Computer Architecture: A Quantitative Approach*, ppg. 472-473]

For multi-core SoCs developed in the Microcontroller Division, a hardware-enforced semaphore implementation as a platform IPS module is used for the following reasons:

- A smaller module size versus a platform reservation monitor for ARM Cortex A5 baseddesigns and it does not introduce any timing-critical paths, for example, the AHB system bus address phase cycle like a reservation monitor
- Provides a more robust implementation with features not possible in a reservation-only approach
- Provides a more generic, architecture-neutral solution, applicable across *all* the processor families supported by the Microcontroller Division

The sole drawback to a hardware-based semaphore module is the limited number of semaphores versus the "infinite" number that can be supported with ARM Cortex A5 based reservation instructions.

24.1.2 Overview

The IPS_Semaphores module provides a platform IPS slave device which implements 16 hardware-enforced gates with the following features:

- Module definition supports 16 hardware-enforced gates in a dual-processor configuration, where cp0 is core processor 0 and cp1 is core processor 1
    - Hardware gates appear as a 16-entry byte-size array with read and write accesses
        - Processors lock gates by writing "processor_number+1" to the appropriate gate and must read back the gate value to verify the lock operation was successful
        - Once locked, the gate is unlocked by a write of zeroes from the locking processor
    - Optional interrupt notification after a failed lock write provides a mechanism to indicate when the gate is unlocked

  - Secure reset mechanisms are supported to clear the contents of individual semaphore gates or notification logic, as well as a clear_all capability
  - Programming model allocates memory space to support up to 8 processors and up to 64 gates
- Memory-mapped IPS platform device
  - Interface to the IPS bus for programming-model accesses
  - Two outputs (one per processor) for interrupt notification of failed lock writes
- Implementation Specifics
  - Module size estimate, based on 130-nm (HiP7A) process technology @ 150 C PVT, is ~2.5 Kgates (nand2_2 equivalents) with no timing issues
  - Implementation includes multiple, independent, but related finite-state machines

A simplified block diagram of the Semaphores module is shown in Figure 24-1. In the diagram, the register blocks named gate0, gate1,…, gate 15 include the finite state machines implementing the semaphore gates plus the interrupt notification logic.

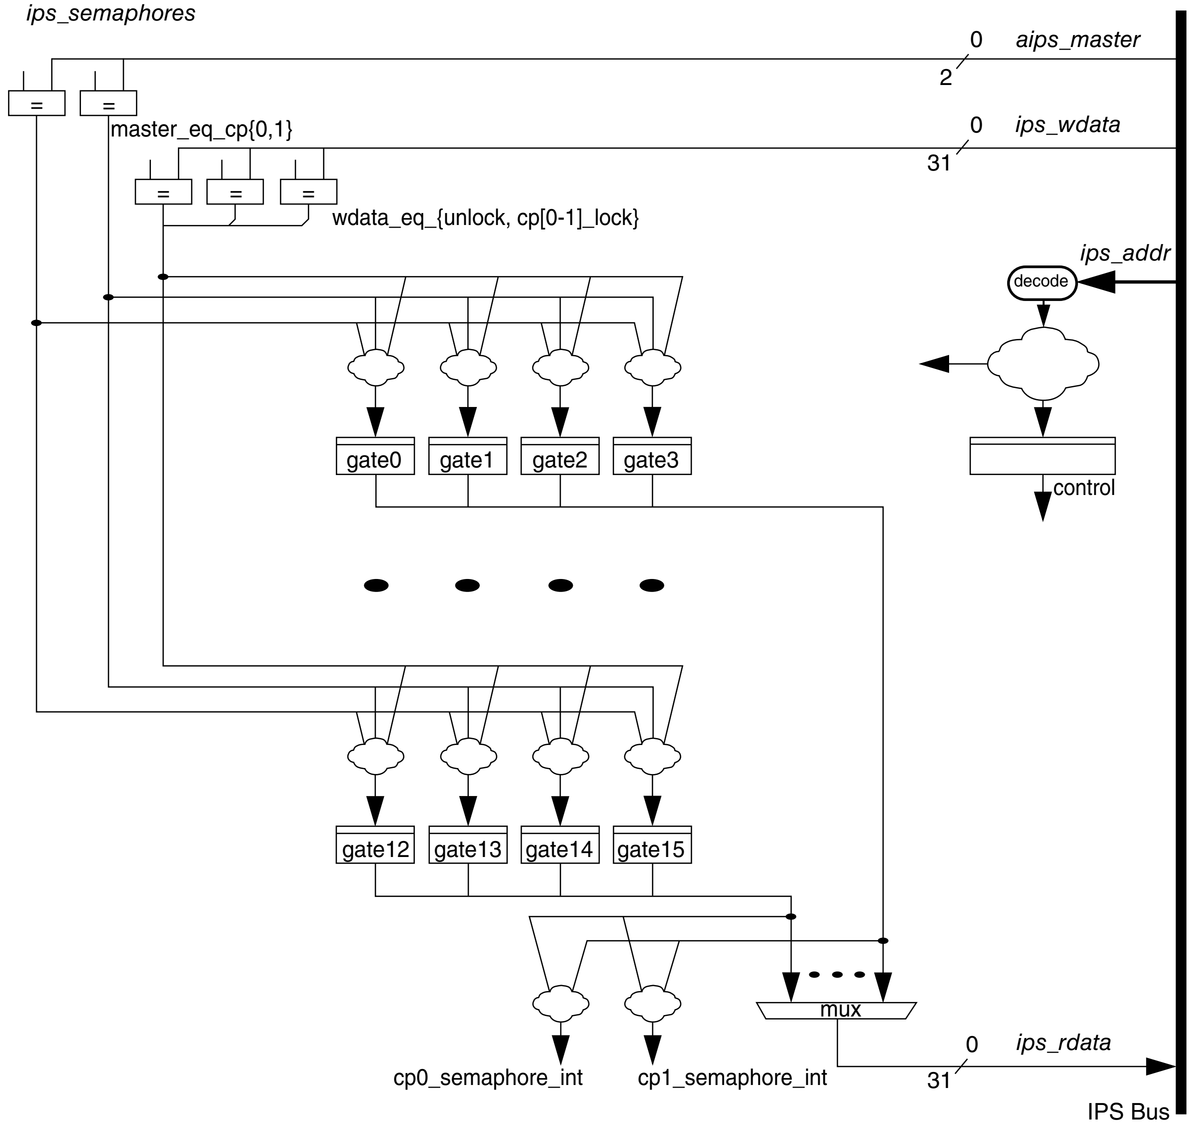

Figure 24-1. IPS_Semaphores Block Diagram

24.1.3 Features

The Semaphores module implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:

- Support for 16 hardware-enforced gates in a dual-processor configuration
  - Each hardware gate appears as a 3-state, 2-bit state machine, with all 16 gates mapped as a byte-size array
    - 3-state implementation

      if gate = 0b00, then state = unlocked
      if gate = 0b01, then state = locked by processor 0

if gate = 0b10, then state = locked by processor 1

- Uses the bus master number as a reference attribute plus the specified data patterns to validate all write operations
- Once locked, the gate can (and must) be unlocked by a write of zeroes from the locking processor

- Optional interrupt notification after a failed lock write provides a mechanism to indicate when the gate is unlocked
- Secure reset mechanisms are supported to clear the contents of individual gates or notification logic, as well as a clear_all capability

- Memory-mapped IPS slave peripheral platform module
    - Interface to the IPS bus for programming-model accesses
    - Two outputs (one per processor) for interrupt notification of failed lock writes

24.1.4 Modes of Operation

The Semaphores module does not support any special modes of operation. As a slave peripheral memory-mapped device located on the platform's IPS slave bus, it responds based strictly on the memory addresses of the connected bus. The IPS bus is used to access the Semaphores ' programming model.

24.2 External Signal Description

The Semaphores module does not include any external interfaces. The Semaphores ' *internal* interface include an IPS connection for accessing the programming model plus interrupt requests for failed lock processor notification. For additional information on the internal interfaces, see IPS_Semaphores Interfaces.

24.3 Memory map and register definition

The Semaphores module provides an IPS programming model mapped to an SPP-standard on-platform 16 KB space. The description here specifies a dual-core configuration with 16 semaphore gates. All the register names are prefixed with "Sema4" as an abbreviation for the full module name.

The programming model is referenced using 8-, 16- and 32-bit accesses. Reads can use any reference size, while writes are generally restricted to the size of the register. Exceptions to the write size restrictions are detailed in the individual register descriptions. Attempted references using inappropriate access sizes, to undefined (reserved) addresses, or with a non-supported access type (for example, a write to a read-only register) generate an IPS error termination.

Finally, the programming model allocates space for a definition with up to 64 gates and up to 8 processor cores, even though this definition is considerably larger than any currently-planned module implementations. The number of gates and supported processor cores are independent; there is no relationship between these two system variables.

The 16 KB Semaphores programming model map is shown in the following table.

SEMA4 memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4001_D000	Semaphores Gate 0 Register (SEMA4_Gate00)	8	R/W	00h	24.3.1/1086

24.3.1 Semaphores Gate 0 Register (SEMA4_Gate00)

Each semaphore gate is implemented in a 2-bit finite state machine, right-justified in a byte data structure. The hardware uses the bus master number in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. 16- and 32-bit writes to multiple gates are allowed, but the write data operand must only update the state of a single gate. A byte write data value of 0x03 is defined as "no operation" and does not affect the state of the corresponding gate register. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes

Address: 4001_D000h base + 0h offset = 4001_D000h

Bit	0	1	2	3	4	5	6	7
Read	0						GTFSM	
Write								
Reset	0	0	0	0	0	0	0	0

SEMA4_Gate00 field descriptions

Field	Description
0–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
6–7 GTFSM	Gate Finite State Machine. Gate Finite State Machine. The hardware gate is maintained in a 3-state implementation-unlocked, locked by processor 0 or locked by processor 1. For more details, see SEMA4_GATEn Operation .

Table continues on the next page...

SEMA4_Gate00 field descriptions (continued)

Field	Description
	NOTE: The state of the gate reflects the last processor that locked it, which can be useful during system debug. 00 The gate is unlocked (free). 01 The gate has been locked by processor 0. 10 The gate has been locked by processor 1. 11 This state encoding is never used and therefore reserved. Attempted writes of 0x03 are treated as "no operation" and do not affect the gate state machine.

24.3.2 Semaphores Gate 1 Register (SEMA4_Gate01)

Each semaphore gate is implemented in a 2-bit finite state machine, right-justified in a byte data structure. The hardware uses the bus master number in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. 16- and 32-bit writes to multiple gates are allowed, but the write data operand must only update the state of a single gate. A byte write data value of 0x03 is defined as "no operation" and does not affect the state of the corresponding gate register. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes

Address: 4001_D000h base + 1h offset = 4001_D001h

24.3.17 Semaphores Processor n IRQ Notification Enable (SEMA4_CP*n*INE)

The application of a hardware semaphore module provides an opportunity for implementation of helpful system-level features. An example is an optional mechanism to generate a processor interrupt after a failed lock attempt. Recall traditional software gate functions execute a spin-wait loop in an effort to obtain and lock the referenced gate. With this module, the processor that fails in the lock attempt could continue with other tasks and allow a properly-enabled notification interrupt to return its execution to the original lock function.

The optional notification interrupt function consists of two registers for each processor: an interrupt notification enable register (SEMA4_CPnINE) and the interrupt request register (SEMA4_CPnNTF). To support implementations with more than 16 gates, these registers can be referenced with aligned 16- or 32-bit accesses. For the SEMA4_CPnINE registers, unimplemented bits read as zeroes, and writes are ignored.

24.3.18 Semaphores Processor n IRQ Notification (SEMA4_CP*n*NTF)

The Semaphores module optionally allows the processor that fails in the lock attempt to continue with other tasks and allow a properly-enabled notification interrupt to return its execution to the original lock function rather than simply execute in a spin-wait loop.

The optional notification interrupt mechanism consists of two registers for each processor: an interrupt notification enable register (SEMA4_CPnINE) and the read-only notification interrupt request register (SEMA4_CPnNTF). To support implementations with more than 16 gates, these registers can be referenced with aligned 16- or 32-bit accesses. For the SEMA4_CPnNTF registers, unimplemented bits read as zeroes.

The notification interrupt is generated via a unique finite state machine, one per hardware gate. This machine operates in the following manner:

1. When an attempted lock fails, the FSM enters a first state where it waits until the gate is unlocked.
2. Once unlocked, the FSM enters a second state where it generates an interrupt request to the “failed lock” processor.
3. When the “failed lock” processor succeeds in locking the gate, the IRQ is automatically negated and the FSM returns to the idle state. However, if the other processor again locks the gate, the FSM returns to the first state, negates the interrupt request, and then waits for the gate to be unlocked (again).

The notification interrupt request is implemented in a 3-bit, 5-state machine, where tw specific states are encoded and program-visible as SEMA4_CP0NTF[GNn] and SEMA4_CP1NTF[GNn].

0–15 GNn	Gate n Notification. This read-only field is a bitmap of the interrupt request notification from a failed attempt to lock gate n. For more details, see SEMA4_CPnNTF Operation .

24.3.19 Semaphores (Secure) Reset Gate n (SEMA4_RSTGT)

Although the intent of the hardware gate implementation specifies a protocol where the locking processor must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the Semaphores module implements a "secure" reset mechanism which allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the specified gate(s). The required access pattern is:

1. A processor performs a 16-bit write to the SEMA4_RSTGT memory location. The most significant byte (SEMA4_RSTGT[RSTGDP]) must be 0xe2; the least significant byte is a "don't_care" for this reference.
2. The same processor then performs a second 16-bit write to the SEMA4_RSTGT location. For this write, the upper byte (SEMA4_RSTGT[RSTGDP]) is the logical complement of the first data pattern (0x1d) and the lower byte (SEMA4_RSTGT[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate be cleared, or that all gates are cleared.
3. Reads of the SEMA4_RSTGT location return information on the 2-bit state machine (SEMA4_RSTGT[RSTGSM]) which implements this function, the bus master performing the reset (SEMA4_RSTGT[RSTGMS]) and the gate number(s) last cleared (SEMA4_RSTGT[RSTGTN]). Reads of the SEMA4_RSTGT register do not affect the secure reset finite state machine in any manner.

Address: 4001_D000h base + 100h offset = 4001_D100h

</table>

24.3.20 Semaphores (Secure) Reset IRQ Notification (SEMA4_RSTNTF)

As with the case of the secure reset function and the hardware gates, it is recognized that system operation may require a reset function to re-initialize the state of the IRQ notification logic without requiring a system-level reset.

To support this special notification reset requirement, the Semaphores module implements a "secure" reset mechanism which allows an IRQ notification (or all the notifications) to be initialized by following a specific dual-write access pattern. When successful, the specified IRQ notification state machine(s) are reset. Using a technique similar to that required for the servicing of a software watchdog timer, the secure reset mechanism requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the IRQ notification(s). The required access pattern is:

1. A processor performs a 16-bit write to the SEMA4_RSTNTF memory location. The most significant byte (SEMA4_RSTNTF[RSTNDP]) must be 0x47; the least significant byte is a "don't_care" for this reference.
2. The same processor then performs a second 16-bit write to the SEMA4_RSTNTF location. For this write, the upper byte (SEMA4_RSTNTF[RSTNDP]) is the logical complement of the first data pattern (0xb8) and the lower byte (SEMA4_RSTNTF[RSTNTN]) specifies the notification(s) to be reset. This field can specify a single notification be cleared, or that all notifications are cleared.
3. Reads of the SEMA4_RSTNTF location return information on the 2-bit state machine (SEMA4_RSTNTF[RSTNSM]) which implements this function, the bus master performing the reset (SEMA4_RSTNTF[RSTNMS]) and the notification number(s) last cleared (SEMA4_RSTNTF[RSTNTN]). Reads of the SEMA4_RSTNTF register do not affect the secure reset finite state machine in any manner.

24.4 Functional Description

In this section, the functional operation of the Semaphores module, specifically the state machines of the SEMA4_GATEn and SEMA4_CPnNTF registers are detailed.

24.4.1 SEMA4_GATEn Operation

Recall each of the SEMA4_GATEn registers implements a 2-bit, 3-state machine. The state transitions for each gate are shown in the following figure.

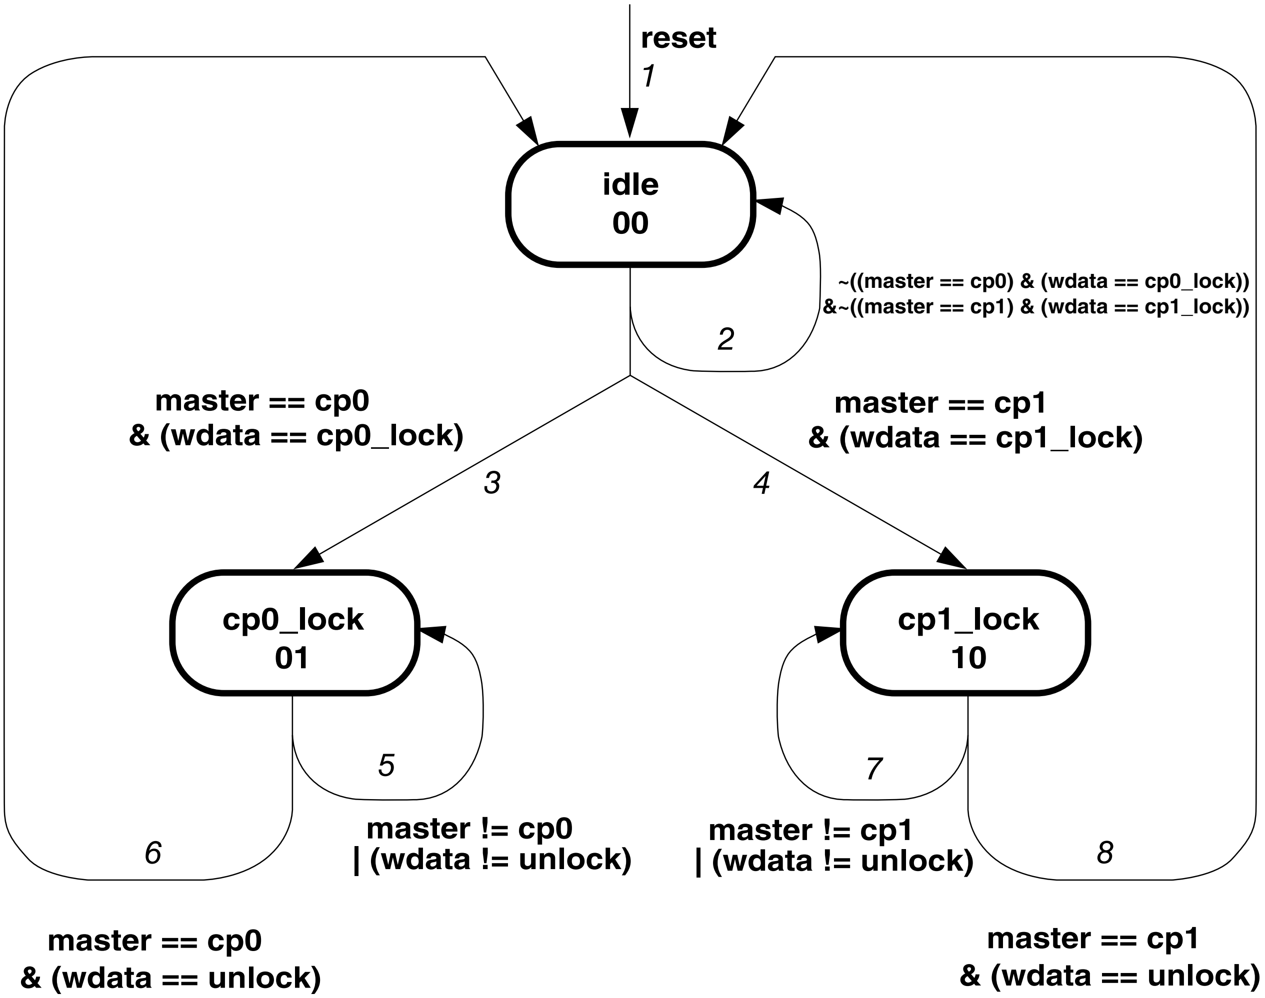

Figure 24-26. SEMA4_GATEn State Machine

The bus master number is used to identify core processor 0 (cp0) or core processor 1 (cp1). The Standard (or Reduced) Product Platform passes the AHB bus master number (`hmaster[2:0]`) through the AIPS (or AIPS-Lite) controller and drives an `aips_master[2:0]` output to the Semaphores module as an IPS sideband signal.

The state transitions for SEMA4_GATEn are defined in the following table.

Table 24-26. SEMA4_GATEn State Transitions

Current State	Next State	Transition	Description
–	idle	1	Any reset, whether a system reset or an individual gate reset, unconditionally forces the gate into the idle state.

Table continues on the next page...

Table 24-26. SEMA4_GATEn State Transitions (continued)

Current State	Next State	Transition	Description
idle	idle	2	Unless a write of the appropriate lock value from the corresponding processor occurs, the gate remains in the idle state.
idle	cp0_lock	3	When a write of the "cp0_lock" data value is initiated by processor 0, the gate transitions into the cp0_lock state.
idle	cp1_lock	4	When a write of the "cp1_lock" value is initiated by processor 1, the gate transitions into the cp1_lock state.
cp0_lock	cp0_lock	5	Once in this state, the gate remains here if any attempted write is not from cp0 with the unlock data value.
cp0_lock	idle	6	The gate returns to the idle (unlocked) state once a write from cp0 with the unlock data value occurs.
cp1_lock	cp1_lock	7	Once in this state, the gate remains here if any attempted write is not from cp1 with the unlock data value.
cp1_lock	idle	8	The gate returns to the idle (unlocked) state once a write from cp1 with the unlock data value occurs.

24.4.2 SEMA4_CPnNTF Operation

The failed lock write notification interrupt request is implemented in a 3-bit, 5-state machine which records failed lock attempts and transitions based on gate locking and unlocking. Two specific states are encoded and program-visible as SEMA4_CP0NTF[GNn] and SEMA4_CP1NTF[GNn]. See the following figure.

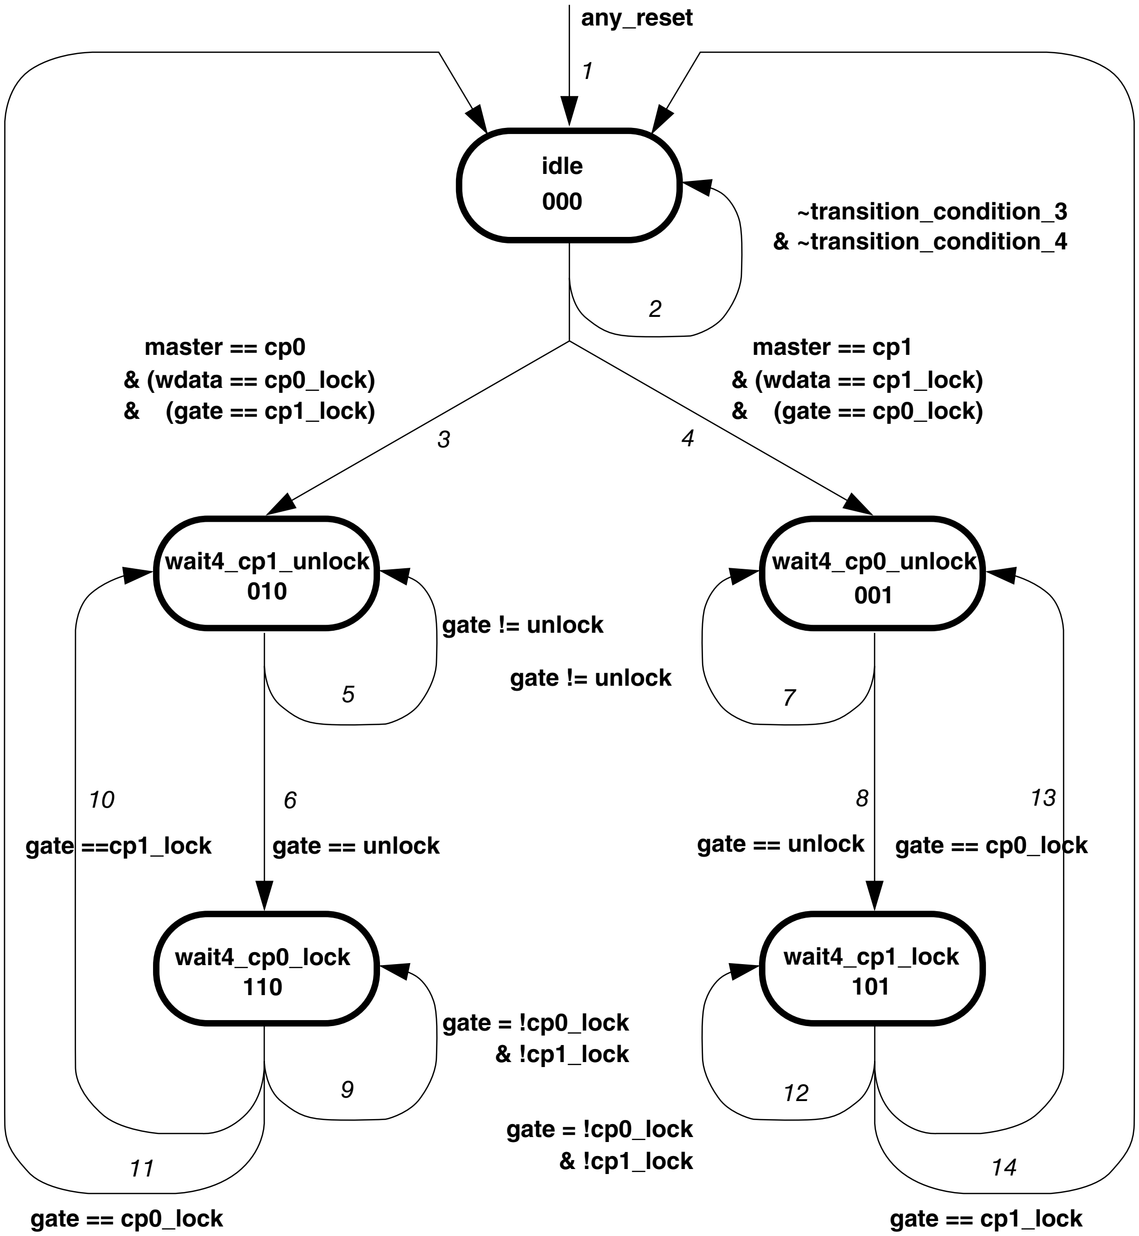

Figure 24-27. IRQ Notification State Machine

The state transitions of the IRQ notification function are defined in the following. Specific states of this machine are program-visible as the SEMA4_CPnNTF registers. In particular, two states are program-visible:

```
if state = wait4_cp0_lock (0b110) // generate cp0_semaphore_int if properly enabled
                then SEMA4_CP0NTF[GNn] = 1; else SEMA4_CP0NTF[GNn] = 0
if state = wait4_cp1_lock (0b101) // generate cp1_semaphore_int if properly enabled
                then SEMA4_CP1NTF[GNn] = 1; else SEMA4_CP1NTF[GNn] = 0
```

Table 24-27. IRQ Notification State Transitions

Current State	Next State	Transition	Description
–	idle	1	Any reset, including a system reset or an individual notification or secure gate reset, unconditionally forces the machine into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding processor to an already-locked gate occurs, the machine remains in the idle state.
idle	wait4_cp1_unlock	3	When a write of the "cp0_lock" data value is initiated by processor 0 but the gate is already locked by cp1, the machine transitions into this state, where it waits for cp1 to unlock the gate.
idle	wait4_cp0_unlock	4	When a write of the "cp1_lock" data value is initiated by processor 1but the gate is already locked by cp0, the machine transitions into this state, where it waits for cp0 to unlock the gate
wait4_cp1_unlock	wait4_cp1_unlock	5	Once in this state, the machine remains here until the gate is unlocked.
wait4_cp1_unlock	wait4_cp0_lock	6	From this state, the machine transitions into the next state, waiting for cp0 to lock the gate, once it has been unlocked.
wait4_cp0_unlock	wait4_cp0_unlock	7	Once in this state, the machine remains here until the gate is unlocked.
wait4_cp0_unlock	wait4_cp1_lock	8	From this state, the machine transitions into the next state, waiting for cp1 to lock the gate, once it has been unlocked.
wait4_cp0_lock	wait4_cp0_lock	9	In this state, the machine generates the notification interrupt (if properly-enabled) and remains here until the gate is locked by processor 0 or the gate is again locked by processor 1.
wait4_cp0_lock	wait4_cp1_unlock	10	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is again locked by processor 1. With this transition, the notification interrupt request is negated.
wait4_cp0_lock	idle	11	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is finally locked by processor 0. With this transition, the notification interrupt request is negated.
wait4_cp1_lock	wait4_cp1_lock	12	In this state, the machine generates the notification interrupt (if properly-enabled) and remains here until the gate is locked by processor 1or the gate is again locked by processor 0.
wait4_cp1_lock	wait4_cp0_unlock	13	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is again locked by processor 0. With this transition, the notification interrupt request is negated.
wait4_cp1_lock	idle	14	In this state, the machine generates the notification interrupt (if properly-enabled) and transitions if the gate is finally locked by processor 1. With this transition, the notification interrupt request is negated.

The Semaphores module generates two interrupt request output signals, one per processor, combining the SEMA4_CPnINE and SEMA4_CPnNTF registers, where the boolean equations are:

```
cp0_semaphore_int
    =    sema4_cp0ine[ine0]    &    sema4_cp0ntf[gn0]
    |    sema4_cp0ine[ine1]    &    sema4_cp0ntf[gn1]
    |    sema4_cp0ine[ine2]    &    sema4_cp0ntf[gn2]
    ...
    |    sema4_cp0ine[ine15]    &    sema4_cp0ntf[gn15]
cp1_semaphore_int
    =    sema4_cp1ine[ine0]    &    sema4_cp1ntf[gn0]
    |    sema4_cp1ine[ine1]    &    sema4_cp1ntf[gn1]
    |    sema4_cp1ine[ine2]    &    sema4_cp1ntf[gn2]
    ...
    |    sema4_cp1ine[ine15]    &    sema4_cp1ntf[gn15]
```

24.5 Initialization Information

The reset state of the IPS_Semaphores module allows it to begin operation without the need for any further initialization. All the internal state machines are cleared by any reset event, allowing the module to immediately begin operation.

24.6 Application Information

In an operational multi-core system, most interactions involving the Semaphores module involves reads and writes to the SEMA4_GATEn registers for implementation of the hardware-enforced software gate functions. Typical code segments for gate functions perform the following operations:

- To lock (close) a gate
  - The processor performs a byte write of "logical_processor_number + 1" to gate[i]
  - The processor reads back gate[i] and checks for a value of "logical_processor_number + 1"

If the compare indicates the expected value

then the gate is locked; proceed with the protected code segment

else

lock operation failed;

repeat process beginning with byte write to gate[i] in spin-wait loop, or

proceed with another execution path and wait for failed lock interrupt notification

A simple C-language example of a `gateLock` function is shown in the following figure. This function follows the Hennessy/Patterson example described in Multi-Core Programming 101: Software Gates.

```
#define UNLOCK      0
#define CP0_LOCK    1
#define CP2_LOCK    2

void gateLock (n)
int   n;                              /* gate number to lock */
{
  int i;
  int current_value;
  int locked_value;

  i = processor_number();  /* obtain logical CPU number */

  if (i == 0)
    locked_value = CP0_LOCK;
  else
    locked_value = CP1_LOCK;

  /* read the current value of the gate and wait until the state == UNLOCK */
  do {
     current_value = gate[n];
  } while (current_value != UNLOCK);

  /* the current value of the gate == UNLOCK. attempt to lock the gate for this
     processor. spin-wait in this loop until gate ownership is obtained */
  do {
    gate[n] = locked_value;  /* write gate with processor_number + 1 */
    current_value = gate[n]; /* read gate to verify ownership was obtained */
  } while (current_value != locked_value);
```

Figure 24-28. Sample gateLock Function

- To unlock (open) a gate
  - After completing the protected code segment, the locking processor performs a byte write of zeroes to gate[i], opening (unlocking) the gate

A few comments on the logical CPU number are appropriate. In this example, a reference to `processor_number()` is used to retrieve this hardware configuration value. Typically, the logical processor numbers are defined by a hardwired input vector to the individual cores. The exact method for accessing the logical processor number varies by architecture. For PowerPC cores, there is a processor ID register (PIR) which is SPR 286 and contains this value. A single instruction can be used to move the contents of the PIR into a general-purpose register: **`mfspr rx,286`** where rx is the destination GPRn. Other architectures may support a specific instruction to move the contents of the logical processor number into a general-purpose register, e.g., **`rdcpn rx`** for a "read CPU number" instruction.

If the optional failed lock IRQ notification mechanisms are used, then accesses to the related registers (SEMA4_CPnINE, SEMA4_ CPnNTF) are required. Note that there is no required negation of the failed lock write notification interrupt as the request is automatically negated by the Semaphores module once the gate has been successfully locked by the "failing" processor.

Finally, in the event a system state requires a software-controlled reset of a gate or IRQ notification register(s), accesses to the secure reset control registers (SEMA4_RSTGT, SEMA4_RSTNTF) are required. For these situations, it is recommended that the appropriate IRQ notification enable(s) (SEMA4_CPnINE) bits be disabled *before* initiating the secure reset 2-write sequence to avoid any race conditions involving spurious notification interrupt requests.

Chapter 25
External Watchdog Monitor (EWM)

25.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The watchdog is generally used to monitor the flow and execution of embedded software within an MCU. The watchdog consists of a counter that if allowed to overflow, forces an internal reset (asynchronous) to all on-chip peripherals and optionally assert the $\overline{\text{RESET}}$ pin to reset external devices/circuits. The overflow of the watchdog counter must not occur if the software code works well and services the watchdog to re-start the actual counter.

For safety, a redundant watchdog system, External Watchdog Monitor (EWM), is designed to monitor external circuits, as well as the MCU software flow. This provides a back-up mechanism to the internal watchdog that resets the MCU's CPU and peripherals.

The EWM differs from the internal watchdog in that it does not reset the MCU's CPU and peripherals. The EWM if allowed to time-out, provides an independent $\overline{\text{EWM\_out}}$ pin that when asserted resets or places an external circuit into a safe mode. The CPU resets the EWM counter that is logically ANDed with an external digital input pin. This pin allows an external circuit to influence the reset_out signal.

25.1.1 Features

Features of EWM module include:

- Independent LPO clock source
- Programmable time-out period specified in terms of number of EWM LPO clock cycles.

- Windowed refresh option
  - Provides robust check that program flow is faster than expected.
  - Programmable window.
  - Refresh outside window leads to assertion of $\overline{\text{EWM\_out}}$.
- Robust refresh mechanism
  - Write values of 0xB4 and 0x2C to EWM Refresh Register within 63 (*EWM_service_time*) peripheral bus clock cycles.
- One output port, $\overline{\text{EWM\_out}}$, when asserted is used to reset or place the external circuit into safe mode.
- One Input port, EWM_in, allows an external circuit to control the $\overline{\text{EWM\_out}}$ signal.

25.1.2 Modes of Operation

This section describes the module's operating modes.

25.1.2.1 Stop Mode

When the EWM is in stop mode, the CPU services to the EWM cannot occur. On entry to stop mode, the EWM's counter freezes.

There are two possible ways to exit from Stop mode:

- On exit from stop mode through a reset, the EWM remains disabled.
- On exit from stop mode by an interrupt, the EWM is re-enabled, and the counter continues to be clocked from the same value prior to entry to stop mode.

Note the following if the EWM enters the stop mode during CPU service mechanism: At the exit from stop mode by an interrupt, refresh mechanism state machine starts from the previous state which means, if first service command is written correctly and EWM enters the stop mode immediately, the next command has to be written within the next 63 (*EWM_service_time*) peripheral bus clocks after exiting from stop mode. User must mask all interrupts prior to executing EWM service instructions.

25.1.2.2 Wait Mode

The EWM module treats the stop and wait modes as the same. EWM functionality remains the same in both of these modes.

25.1.2.3 Debug Mode

Entry to debug mode has no effect on the EWM.

- If the EWM is enabled prior to entry of debug mode, it remains enabled.
- If the EWM is disabled prior to entry of debug mode, it remains disabled.

25.1.3 Block Diagram

This figure shows the EWM block diagram.

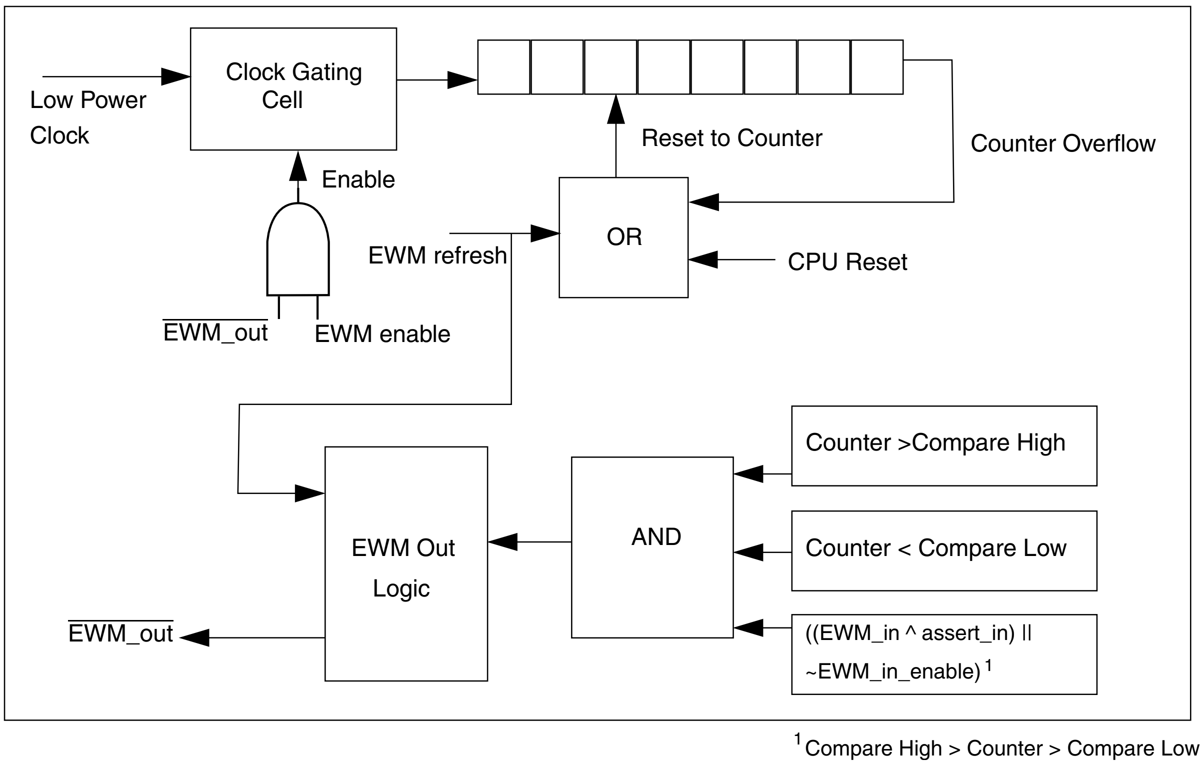

Figure 25-1. EWM Block Diagram

25.2 EWM Signal Descriptions

The EWM has two external signals and internal options for the counter clock sources, as shown in the following table.

Table 25-1. EWM Signal Descriptions

Signal	Description	I/O
EWM_in	EWM input for safety status of external safety circuits. The polarity of EWM_in is programmable using the EWM_CTRL[ASSIN] bit. The default polarity is active-low.	I
$\overline{\text{EWM\_out}}$	EWM reset out signal	O
lpo_clk[3:0]	Low power clock sources for running counter All four lpo_clk clocks are SOSC clocks.	I

25.3 Memory Map/Register Definition

This section contains the module memory map and registers.

EWM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4006_5000	Control Register (EWM_CTRL)	8	R/W	00h	25.3.1/1120
4006_5001	Service Register (EWM_SERV)	8	W (always reads 0)	00h	25.3.2/1121
4006_5002	Compare Low Register (EWM_CMPL)	8	R/W	00h	25.3.3/1122
4006_5003	Compare High Register (EWM_CMPH)	8	R/W	FFh	25.3.4/1122
4006_5004	Clock Control Register (EWM_CLKCTRL)	8	R/W	00h	25.3.5/1123
4006_5005	Clock Prescaler Register (EWM_CLKPRESCALER)	8	R/W	00h	25.3.6/1123

25.3.1 Control Register (EWM_CTRL)

The CTRL register is cleared by any reset.

NOTE

INEN, ASSIN and EWMEN bits can be written once after a CPU reset. Modifying these bits more than once, generates a bus transfer error.

Address: 4006_5000h base + 0h offset = 4006_5000h

Bit	7	6	5	4	3	2	1	0
Read	0				INTEN	INEN	ASSIN	EWMEN
Write								
Reset	0	0	0	0	0	0	0	0

EWM_CTRL field descriptions

Field	Description
7–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 INTEN	Interrupt Enable. This bit when set and EWM_out is asserted, an interrupt request is generated. To de-assert interrupt request, user should clear this bit by writing 0.
2 INEN	Input Enable. This bit when set, enables the EWM_in port.
1 ASSIN	EWM_in's Assertion State Select. Default assert state of the EWM_in signal is logic zero. Setting ASSIN bit inverts the assert state to a logic one.
0 EWMEN	EWM enable. This bit when set, enables the EWM module. This resets the EWM counter to zero and deasserts the EWM_out signal. Clearing EWMEN bit disables the EWM, and therefore it cannot be enabled until a reset occurs, due to the write-once nature of this bit.

25.3.2 Service Register (EWM_SERV)

The SERV register provides the interface from the CPU to the EWM module. It is write-only and reads of this register return zero.

Address: 4006_5000h base + 1h offset = 4006_5001h

Bit	7	6	5	4	3	2	1	0
Read	0							
Write	SERVICE							
Reset	0	0	0	0	0	0	0	0

EWM_SERV field descriptions

Field	Description
7–0 SERVICE	The EWM service mechanism requires the CPU to write two values to the SERV register: a first data byte of 0xB4, followed by a second data byte of 0x2C. The EWM service is illegal if either of the following conditions is true. • The first or second data byte is not written correctly. • The second data byte is not written within a fixed number of peripheral bus cycles of the first data byte. This fixed number of cycles is called *EWM_service_time*.

25.3.3 Compare Low Register (EWM_CMPL)

The CMPL register is reset to zero after a CPU reset. This provides no minimum time for the CPU to service the EWM counter.

NOTE

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

Address: 4006_5000h base + 2h offset = 4006_5002h

Bit	7	6	5	4	3	2	1	0
Read Write	COMPAREL							
Reset	0	0	0	0	0	0	0	0

EWM_CMPL field descriptions

Field	Description
7–0 COMPAREL	To prevent runaway code from changing this field, software should write to this field after a CPU reset even if the (default) minimum service time is required.

25.3.4 Compare High Register (EWM_CMPH)

The CMPH register is reset to 0xFF after a CPU reset. This provides a maximum of 256 clocks time, for the CPU to service the EWM counter.

NOTE

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

NOTE

The valid values for CMPH are up to 0xFE because the EWM counter never expires when CMPH = 0xFF. The expiration happens only if EWM counter is greater than CMPH.

Address: 4006_5000h base + 3h offset = 4006_5003h

Bit	7	6	5	4	3	2	1	0
Read Write	COMPAREH							
Reset	1	1	1	1	1	1	1	1

EWM_CMPH field descriptions

Field	Description
7–0 COMPAREH	To prevent runaway code from changing this field, software should write to this field after a CPU reset even if the (default) maximum service time is required.

25.3.5 Clock Control Register (EWM_CLKCTRL)

This CLKCTRL register is reset to 0x00 after a CPU reset.

NOTE

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

NOTE

User should select the required low power clock before enabling the EWM.

Address: 4006_5000h base + 4h offset = 4006_5004h

Bit	7	6	5	4	3	2	1	0
Read	0						CLKSEL	
Write								
Reset	0	0	0	0	0	0	0	0

EWM_CLKCTRL field descriptions

Field	Description
7–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–0 CLKSEL	EWM has 4 possible low power clock sources for running EWM counter. One of the clock source can be selected by writing into this field. • 00 - lpo_clk[0] will be selected for running EWM counter. • 01 - lpo_clk[1] will be selected for running EWM counter. • 10 - lpo_clk[2] will be selected for running EWM counter. • 11 - lpo_clk[3] will be selected for running EWM counter.

25.3.6 Clock Prescaler Register (EWM_CLKPRESCALER)

This CLKPRESCALER register is reset to 0x00 after a CPU reset.

NOTE

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.

NOTE

Write the required prescaler value before enabling the EWM.

NOTE

The implementation of this register is chip-specific. See the Chip Configuration details.

Address: 4006_5000h base + 5h offset = 4006_5005h

Bit	7	6	5	4	3	2	1	0
Read Write	CLK_DIV							
Reset	0	0	0	0	0	0	0	0

EWM_CLKPRESCALER field descriptions

Field	Description
7–0 CLK_DIV	Selected low power source for running the EWM counter can be prescaled as below. • Prescaled clock frequency = low power clock source frequency/ (1+ CLK_DIV)

25.4 Functional Description

The following sections describe functional details of the EWM module.

25.4.1 The $\overline{\text{EWM\_out}}$ Signal

The $\overline{\text{EWM\_out}}$ is a digital output signal used to gate an external circuit (application specific) that controls critical safety functions. For example, the $\overline{\text{EWM\_out}}$ could be connected to the high voltage transistors circuits that control an AC motor in a large appliance.

The $\overline{\text{EWM\_out}}$ signal remains deasserted when the EWM is being regularly serviced by the CPU within the programmable service window, indicating that the application code is executed as expected.

The $\overline{\text{EWM\_out}}$ signal is asserted in any of the following conditions:

- Servicing the EWM when the counter value is less than CMPL value.
- If the EWM counter value reaches the CMPH value, and no EWM service has occurred.
- Servicing the EWM when the counter value is more than CMPL and less than CMPH values and EWM_in signal is asserted.

- If functionality of EWM_in pin is enabled and EWM_in pin is asserted while servicing the EWM.
- After any reset (by the virtue of the external pull-down mechanism on the EWM_out pin)

On a normal reset, the EWM_out is asserted. To deassert the EWM_out, set EWMEN bit in the CTRL register to enable the EWM.

If the EWM_out signal shares its pad with a digital I/O pin, on reset this actual pad defers to being an input signal. It takes the EWM_out output condition only after you enable the EWM by the EWMEN bit in the CTRL register.

When the EWM_out pin is asserted, it can only be deasserted by forcing a MCU reset.

Note

EWM_out pad must be in pull down state when EWM functionality is used and when EWM is under Reset.

25.4.2 The EWM_in Signal

The EWM_in is a digital input signal that allows an external circuit to control the EWM_out signal. For example, in the application, an external circuit monitors a critical safety function, and if there is fault with this circuit's behavior, it can then actively initiate the EWM_out signal that controls the gating circuit.

The EWM_in signal is ignored if the EWM is disabled, or if INEN bit of CTRL register is cleared, as after any reset.

On enabling the EWM (setting the CTRL[EWMEN] bit) and enabling EWM_in functionality (setting the CTRL[INEN] bit), the EWM_in signal must be in the deasserted state prior to the CPU servicing the EWM. This ensures that the EWM_out stays in the deasserted state; otherwise, the EWM_out pin is asserted.

Note

You must update the CMPH and CMPL registers prior to enabling the EWM. After enabling the EWM, the counter resets to zero, therefore providing a reasonable time after a power-on reset for the external monitoring circuit to stabilize and ensure that the EWM_in pin is deasserted.

25.4.3 EWM Counter

It is an 8-bit ripple counter fed from a clock source that is independent of the peripheral bus clock source. As the preferred time-out is between 1 ms and 100 ms the actual clock source should be in the kHz range.

The counter is reset to zero, after a CPU reset, or a EWM refresh cycle. The counter value is not accessible to the CPU.

25.4.4 EWM Compare Registers

The compare registers CMPL and CMPH are write-once after a CPU reset and cannot be modified until another CPU reset occurs.

The EWM compare registers are used to create a service window, which is used by the CPU to service/refresh the EWM module.

- If the CPU services the EWM when the counter value lies between CMPL value and CMPH value, the counter is reset to zero. This is a legal service operation.
- If the CPU executes a EWM service/refresh action outside the legal service window, $\overline{\text{EWM\_out}}$ is asserted.

It is illegal to program CMPL and CMPH with same value. In this case, as soon as counter reaches (CMPL + 1), $\overline{\text{EWM\_out}}$ is asserted.

25.4.5 EWM Refresh Mechanism

Other than the initial configuration of the EWM, the CPU can only access the EWM by the EWM Service Register. The CPU must access the EWM service register with correct write of unique data within the windowed time frame as determined by the CMPL and CMPH registers. Therefore, three possible conditions can occur:

Table 25-9. EWM Refresh Mechanisms

Condition	Mechanism
A unique EWM service occurs when CMPL < Counter < CMPH.	The software behaves as expected and the counter of the EWM is reset to zero, and $\overline{\text{EWM\_out}}$ pin remains in the deasserted state. **Note:** EWM_in pin is also assumed to be in the deasserted state.
A unique EWM service occurs when Counter < CMPL	The software services the EWM and therefore resets the counter to zero and asserts the $\overline{\text{EWM\_out}}$ pin (irrespective of the EWM_in pin). The $\overline{\text{EWM\_out}}$ pin is expected to gate critical safety circuits.

Table continues on the next page...

Table 25-9. EWM Refresh Mechanisms (continued)

Condition	Mechanism
Counter value reaches CMPH prior to a unique EWM service	The counter value reaches the CMPH value and no service of the EWM resets the counter to zero and assert the $\overline{\text{EWM\_out}}$ pin (irrespective of the EWM_in pin). The $\overline{\text{EWM\_out}}$ pin is expected to gate critical safety circuits.

Any illegal service on EWM has no effect on $\overline{\text{EWM\_out}}$.

25.4.6 EWM Interrupt

When $\overline{\text{EWM\_out}}$ is asserted, an interrupt request is generated to indicate the assertion of the EWM reset out signal. This interrupt is enabled when CTRL[INTEN] is set. Clearing this bit clears the interrupt request but does not affect $\overline{\text{EWM\_out}}$. The $\overline{\text{EWM\_out}}$ signal can be deasserted only by forcing a system reset.

25.4.7 Selecting the EWM counter clock

There are four possible low power clock sources for the EWM counter. Select one of the available clock sources by programming CLKCTRL[CLKSEL].

25.4.8 Counter clock prescaler

The EWM counter clock source can be prescaled by a clock divider, by programming CLKPRESCALER[CLK_DIV]. This divided clock is used to run the EWM counter.

NOTE

The divided clock used to run the EWM counter must be no more than half the frequency of the bus clock.

Chapter 26
Watchdog Timer (WDOG)

26.1 Overview

The Watchdog Timer (WDOG) protects against system failures by providing a method by which to escape from unexpected events or programming errors.

Once the WDOG is activated, it must be serviced by the software on a periodic basis. If servicing does not take place, the timer times out. Upon timeout, the WDOG asserts the internal system reset signal, $\overline{\text{wdog\_rst}}$, to the System Reset Controller (SRC).

Flow diagrams for the timeout counter shown in .

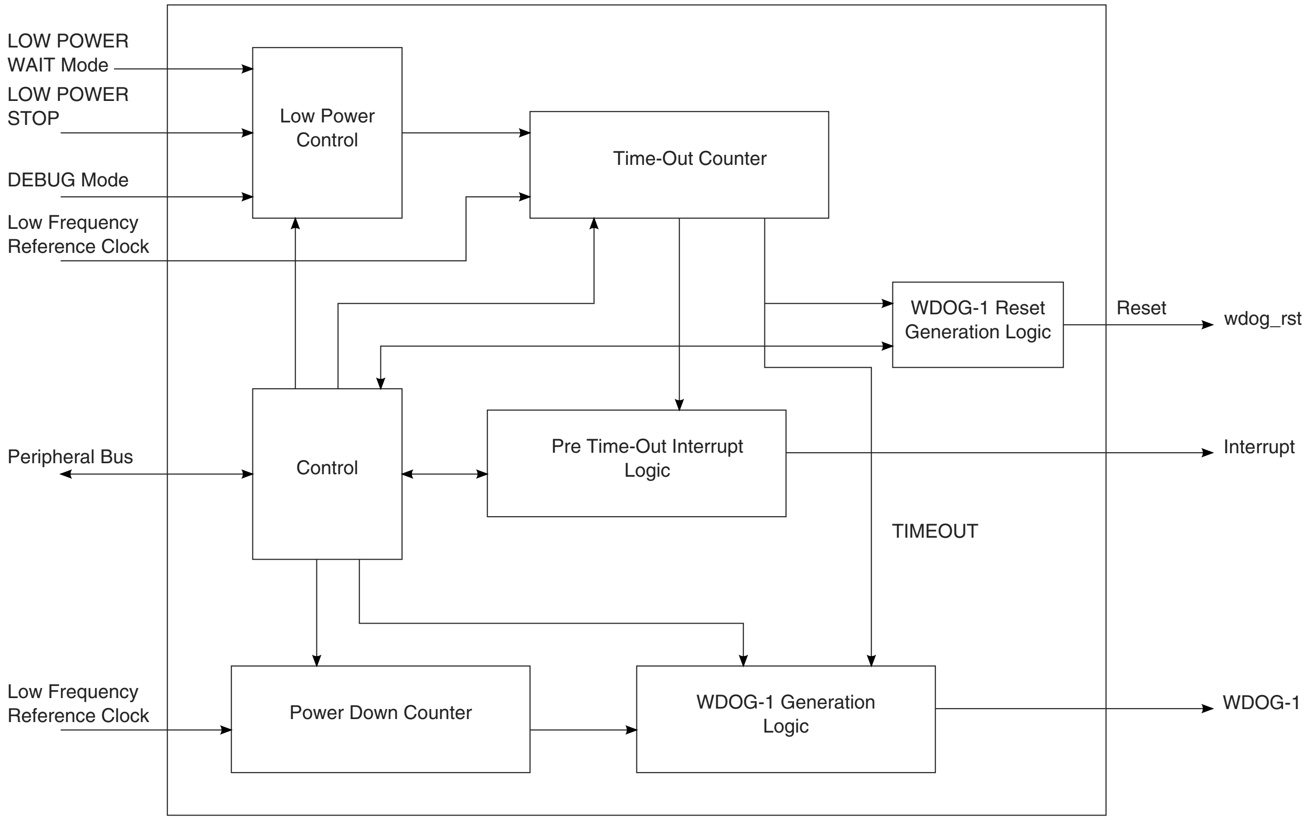

Figure 26-1.

26.1.1 Features

The WDOG features are listed below:

- Configurable timeout counter with timeout periods from 0.5 to 128 seconds which, after timeout expiration, result in the assertion of WDOG_RESET_B_DEB reset signal .
- Time resolution of 0.5 seconds
- Configurable timeout counter that can be programmed to run or stop during low-power modes
- Configurable timeout counter that can be programmed to run or stop during DEBUG mode

26.2 External signals

Table 26-1. Off-chip block signals

Signal	I/O	Description	Reset State[1]	Pull-Up/ Down
$\overline{\text{WDOG}}$	O	This signal will power down the chip. See WDOG_B generation.	1	-
$\overline{\text{wdog\_rst}}$	O	This signal is a reset source for the chip. See Watchdog reset generation.	1	-

1. The reset state values and pull-up/down requirements provided in this table are from the block-level perspective. To understand how the block is integrated at the SoC level, the system software developer must see discussions of the block in the appropriate SoC-level chapter(s). For example, a block signal that requires a pull-up could be integrated with a pull-up option built into the SoC. In this case, the system software developer must ensure the proper programming at the SoC level.

26.3 Clocks

This section describes clocks and special clocking requirements of the block.

The WDOG uses the low frequency reference clock for its counter and control operations. The peripheral bus clock is used for register read/write operations.

The low frequency reference clock is a free-running clock and can't be gated. The peripheral bus clock can't be gated and is selectively switched ON whenever read/write operations takes place.

26.4 Functional description

This section provides a complete functional description of the block.

26.4.1 Timeout event

The WDOG provides timeout periods from 0.5 to 128 seconds with a time resolution of 0.5 seconds.

The user can determine the timeout period by writing to the WDOG timeout field (WT[7:0]) in the Watchdog Control Register (WDOG_WCR). The WDOG must be enabled by setting the WDE bit of Watchdog Control Register (WDOG_WCR) for the timeout counter to start running. After the WDOG is enabled, the counter is activated, loads the timeout value and begins to count down from this programmed value. The timer will time out when the counter reaches zero and

However, the timeout condition can be prevented by reloading the counter with the new timeout value (WT[7:0] of WDOG_WCR) if a service routine (see Servicing WDOG to reload the counter) is performed before the counter reaches zero. If any system errors occur which prevent the software from servicing the Watchdog Service Register (WDOG_WSR), the timeout condition occurs. By performing the service routine, the WDOG reloads its counter to the timeout value indicated by bits WT[7:0] of the Watchdog Control Register (WDOG_WCR) and it restarts the countdown.

A system reset will reset the counter and place it in the idle state at any time during the countdown. The counter flow diagram is shown in .

NOTE

The timeout value is reloaded to the counter either at the time WDOG is enabled or after the service routine has been performed.

26.4.1.1 Servicing WDOG to reload the counter

To reload a timeout value to the counter the proper service sequence begins by writing 0x-5555 followed by 0x-AAAA to the Watchdog Service Register (WDOG_WSR). Any number of instructions can be executed between the two writes. If the WDOG_WSR is not loaded with 0x-5555 prior to writing 0x-AAAA to the WDOG_WSR, the counter is not reloaded. If any value other than 0x-AAAA is written to the WDOG_WSR after 0x-5555, the counter is not reloaded. This service sequence will reload the counter with the timeout value WT[7:0] of Watchdog Control Register (WDOG_WCR). The timeout value can be changed at any point; it is reloaded when WDOG is serviced by the core.

26.4.2 Low power modes

26.4.2.1 STOP mode

If the WDOG timer disable bit for low power STOP mode (WDZST) bit in the Watchdog Control Register (WDOG_WCR), is cleared, the WDOG timer continues to operate using the low frequency reference clock. If the low power enable (WDZST) bit is set, the WDOG timer operation will be suspended in low power STOP mode. Upon exiting low power STOP mode, the WDOG operation returns to what it was prior to entering the STOP mode.

26.4.3 Debug mode

The WDOG timer can be configured for continual operation, or for suspension during debug mode. If the WDOG debug enable (WDBG) bit is set in the Watchdog Control Register (WDOG_WCR), the WDOG timer operation is suspended in debug mode. Register read and write accesses in debug mode continue to function normally. Also, while in debug mode, the WDE bit of Watchdog Control Register (WDOG_WCR) can be enabled/disabled directly. If the WDOG debug enable (WDBG) bit is cleared then WDOG timer operation is not suspended. The power-down counter is not affected by debug mode entry/exit.

NOTE

If the WDE bit of Watchdog Control Register (WDOG_WCR) is set/cleared while in debug mode, it remains set/cleared even after exiting debug mode.

26.4.4 Operations

26.4.4.1 Watchdog reset generation

The WDOG generated reset signal $\overline{\text{wdog\_rst}}$ is asserted by the following operations:

- A software write to the Software Reset Signal (SRS) bit of the Watchdog Control Register (WDOG_WCR).
- WDOG timeout. See Timeout event.

The $\overline{\text{wdog\_rst}}$ will be asserted for one clock cycle of low frequency reference clock for a timeout condition. It remains asserted for 1 clock cycle of low frequency reference clock even if a system reset is asserted in between.

26.4.4.2 WDOG_B generation

The WDOG asserts WDOG_B in the following scenarios:

- Software write to WDA bit of Watchdog Control Register (WDOG_WCR). WDOG_B signal remains asserted as long as the WDA bit is "0".
-

26.4.5 Reset

The block is reset by a system reset and the WDOG counter will be disabled.

26.4.6 Flow Diagrams

A flow diagram of WDOG operation is shown in .

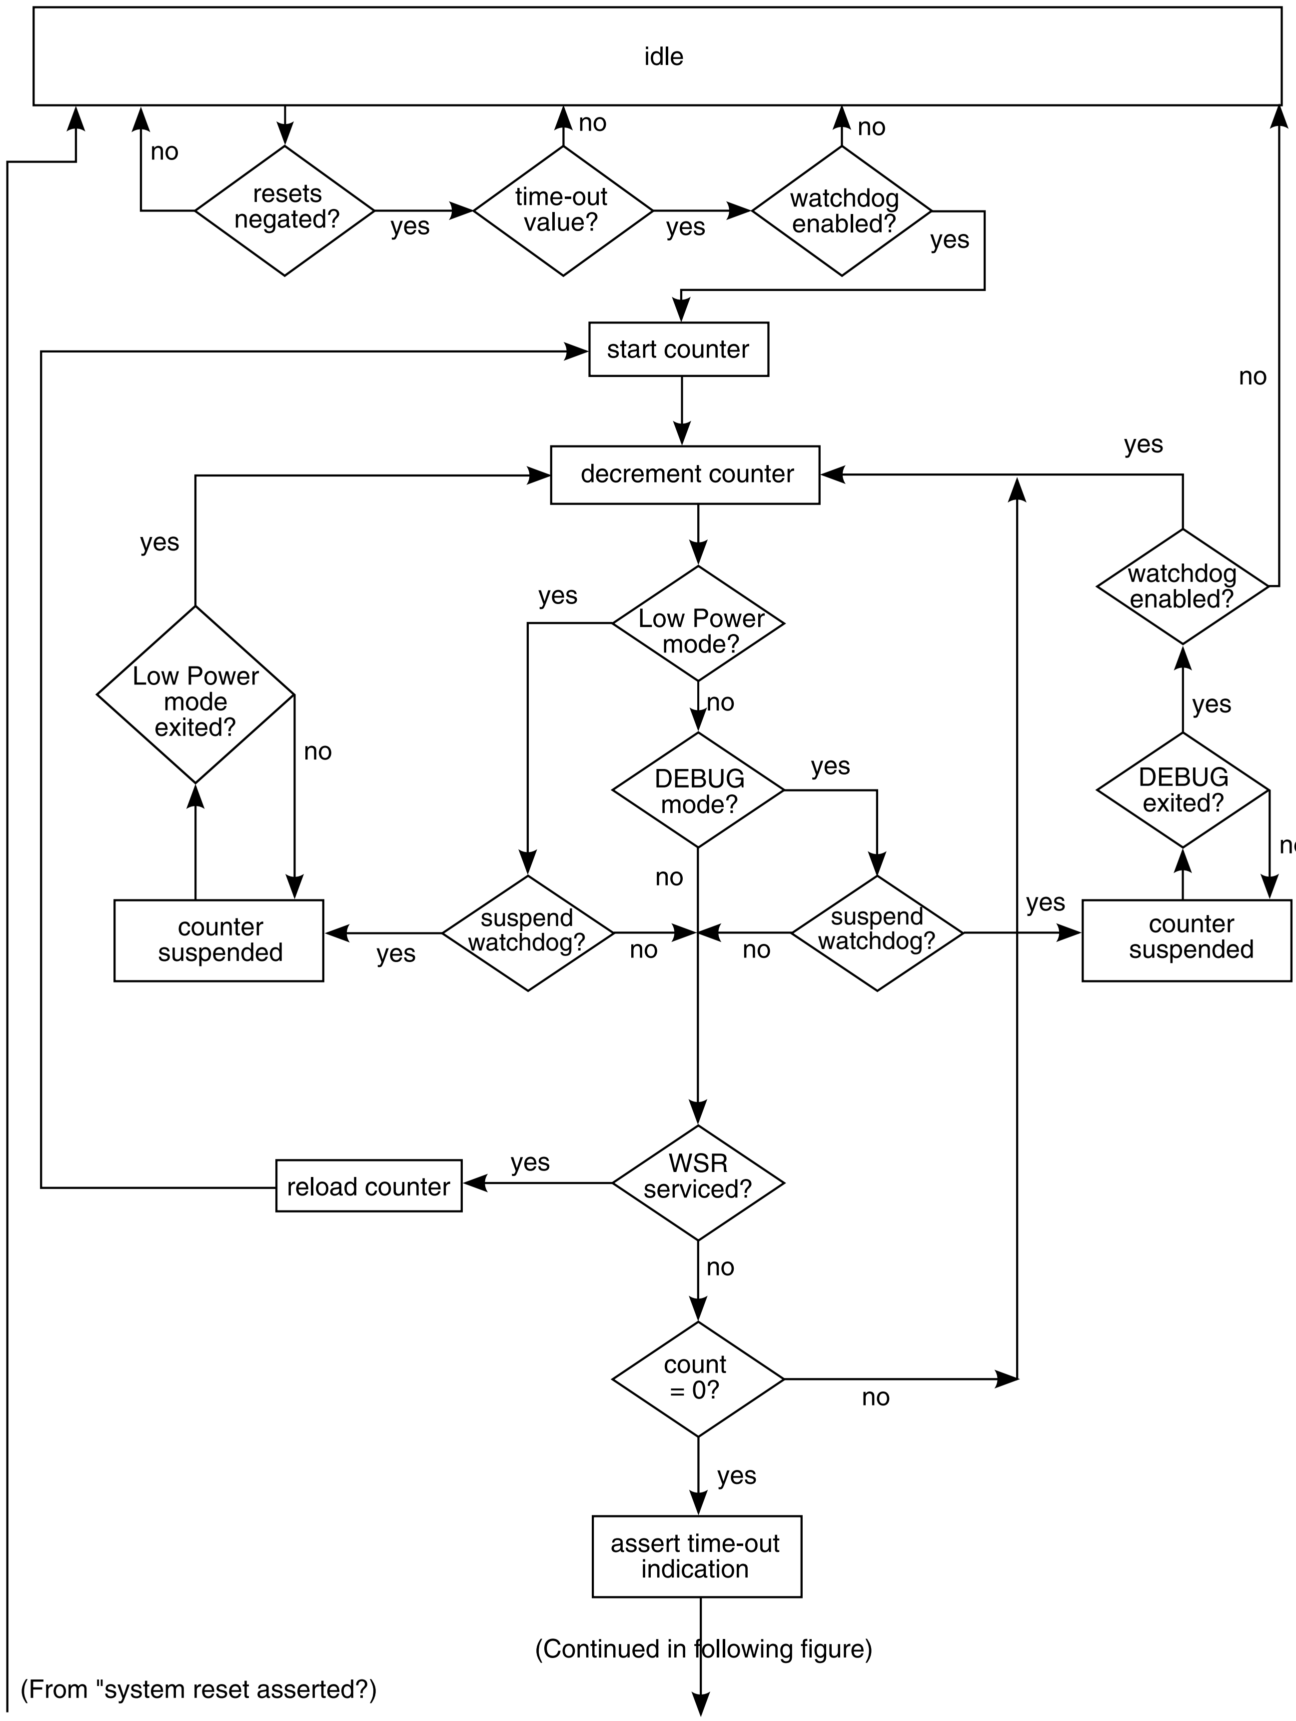

Figure 26-2. Time-Out Counter Flow Diagram

26.5 Initialization

The following sequence should be performed for WDOG initialization.

- WDT field of Watchdog Control Register (WDOG_WCR) should be programmed for sufficient timeout value.
- WDOG should be enabled by setting WDE bit of Watchdog Control Register (WDOG_WCR) so that the timeout counter loads the WDT field value of Watchdog Control Register (WDOG_WCR) and starts counting.

26.6 WDOG Memory Map/Register Definition

The WDOG has user-accessible, 16-bit registers used to configure, operate, and monitor the state of the Watchdog Timer. Byte operations can be performed on these registers. If a 32-bit access is performed,the WDOG will not generate a peripheral bus error but will behave normally, like a 16-Bit access, making read/write possible. A 32-Bit access should be avoided, as the system may go to an unknown state.

WDOG memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
0	Watchdog Control Register (WDOG_WCR)	16	R/W	0030h	26.6.1/1136
2	Watchdog Service Register (WDOG_WSR)	16	R/W	0000h	26.6.2/1138
4	Watchdog Reset Status Register (WDOG_WRSR)	16	R	0000h	26.6.3/1138

26.6.1 Watchdog Control Register (WDOG_WCR)

The Watchdog Control Register (WDOG_WCR) controls the WDOG operation.

- WDE is a write one once only bit. Once software performs a write "1" operation to this bit it cannot be reset/cleared until the next system reset.

Address: 0h base + 0h offset = 0h

Bit	15	14	13	12	11	10	9	8
Read Write	WT							
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read Write	SRE	WDA	SRS	WDE	WDBG	WDZST		
Reset		0	1	1		0	0	0

WDOG_WCR field descriptions

Field	Description
15–8 WT	Watchdog Time-out Field. This 8-bit field contains the time-out value that is loaded into the Watchdog counter after the service routine has been performed or after the Watchdog is enabled. After reset, WT[7:0] must have a value written to it before enabling the Watchdog otherwise count value of zero which is 0.5 seconds is loaded into the counter. **NOTE:** The time-out value can be written at any point of time but it is loaded to the counter at the time when WDOG is enabled or after the service routine has been performed. For more information see Timeout event . 0x00 - 0.5 Seconds (Default). 0x01 - 1.0 Seconds. 0x02 - 1.5 Seconds. 0x03 - 2.0 Seconds. 0xff - 128 Seconds.
6 SRE	software reset extension, an option way to generate software reset adopt a new way to generate a more robust software reset. This bit can be set/clear with IP bus and will be reset with power-on reset . 0 using original way to generate software reset (default) 1 using new way to generate software reset.
5 WDA	WDOG_B assertion. Controls the software assertion of the WDOG_B signal. 0 Assert WDOG_B output. 1 No effect on system (Default).
4 SRS	Software Reset Signal. Controls the software assertion of the WDOG-generated reset signal $\overline{\text{wdog\_rst}}$. This bit automatically resets to "1" after it has been asserted to "0". **NOTE:** This bit does not generate the software reset to the block. 0 Assert system reset signal. 1 No effect on the system (Default).
2 WDE	Watchdog Enable. Enables or disables the WDOG block. This is a write one once only bit. It is not possible to clear this bit by a software write, once the bit is set. **NOTE:** This bit can be set/reset in debug mode (exception). 0 Disable the Watchdog (Default). 1 Enable the Watchdog.
1 WDBG	Watchdog DEBUG Enable. Determines the operation of the WDOG during DEBUG mode. This bit is write once only. 0 Continue WDOG timer operation (Default). 1 Suspend the watchdog timer.
0 WDZST	Watchdog Low Power. Determines the operation of the WDOG during low-power modes. This bit is write once-only.

Table continues on the next page...

WDOG_WCR field descriptions (continued)

Field	Description
	NOTE: The WDOG can continue/suspend the timer operation in the low-power modes (STOP mode). 0 Continue timer operation (Default). 1 Suspend the watchdog timer.

26.6.2 Watchdog Service Register (WDOG_WSR)

When enabled, the WDOG requires that a service sequence be written to the Watchdog Service Register (WSR) to prevent the timeout condition.

NOTE

Executing the service sequence will reload the WDOG timeout counter.

Address: 0h base + 2h offset = 2h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	WSR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

WDOG_WSR field descriptions

Field	Description
15–0 WSR	Watchdog Service Register. This 16-bit field contains the Watchdog service sequence. Both writes must occur in the order listed prior to the time-out, but any number of instructions can be executed between the two writes. The service sequence must be performed as follows: 0x5555 Write to the Watchdog Service Register (WDOG_WSR). 0xAAAA Write to the Watchdog Service Register (WDOG_WSR).

26.6.3 Watchdog Reset Status Register (WDOG_WRSR)

The WRSR is a read-only register that records the source of the output reset assertion. It is not cleared by a hard reset. Therefore, only one bit in the WRSR will always be asserted high. The register will always indicate the source of the last reset generated due to WDOG. Any write performed on this register will generate a Peripheral Bus Error .

A reset can be generated by the following sources, as listed in priority from highest to lowest:

- Watchdog Time-out
- Software Reset

Address: 0h base + 4h offset = 4h

Bit	15	14	13	12	11	10	9	8
Read	0							
Write								
Reset	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Read	0			POR	0		TOUT	SFTW
Write								
Reset	0	0	0	0	0	0	0	0

WDOG_WRSR field descriptions

Field	Description
15–5 Reserved	This read-only field is reserved and always has the value 0.
4 POR	Power On Reset. Indicates whether the reset is the result of a power on reset. 0 Reset is not the result of a power on reset. 1 Reset is the result of a power on reset.
3–2 Reserved	This read-only field is reserved and always has the value 0.
1 TOUT	Timeout. Indicates whether the reset is the result of a WDOG timeout. 0 Reset is not the result of a WDOG timeout. 1 Reset is the result of a WDOG timeout.
0 SFTW	Software Reset. Indicates whether the reset is the result of a WDOG software reset by asserting SRS bit 0 Reset is not the result of a software reset. 1 Reset is the result of a software reset.

Chapter 27
Watchdog Configuration

27.1 Watchdog Scheme

The following three Watchdogs are included in this device:

a) General Purpose WDOG (WDOG-A5) - Monitors A5

b) General Purpose WDOG (WDOG-M4) - Monitors CM4

c) TrustZone Watchdog (WDOG - SNVS) - Part of TrustZone and monitors Secure world

NOTE

Above does not include another WDOG that is part of A5 core complex (CA5-internal) that runs on core clock.

WDOG_SNVS is another instance of the general purpose WDOG mainly intended for secure platforms and with the WDOG reset being controlled by CSU. Since WDOG_SNVS monitors secure word, TZ-WDOG does not have any significance for non-secure parts.

Table 27-1. WDOG Configuration

Configuration	Security	WDOG-SNVS	WDOG-A5	WDOG-M4	Comments
A5 only configuration	Enabled	Functional	Functional	Disabled	
A5 only configuration	Disabled	Disabled	Functional	Disabled	
M4 only Configuration	Enabled	Enabled	Disabled	Functional	
M4 only Configuration	Disabled	Disabled	Disabled	Functional	
Dual Core(A5 Primary)	Enabled	Functional	Functional	Functional	

Table continues on the next page...

Table 27-1. WDOG Configuration (continued)

Configuration	Security	WDOG-SNVS	WDOG-A5	WDOG-M4	Comments
Dual Core (A5 Primary)	Disabled	Disabled	Functional	Functional	
Dual Core (M4 Primary)	Enabled	INVALID Configuration			Security cannot be enabled with M4 as primary core
Dual Core (M4 Primary)	Disabled	Disabled	Functional	Functional	Security Switch should automatically disable or ignore WDOG_SNVS

NOTE

1. TZ-WDOG is only relevant for secure parts as this part of Trust Zone.

All WDOGs are disabled by default (after the reset). WDOG-A5, WDOG-M4 will be configured during the boot while WDOG-SNVS is dedicated for secure world purposes and will be activated by TZ Software if required.

- If servicing does not take place, the timer times out and WDOG reset signal activated
- Interrupt can be generated before the counter actually times out
- wdog_rst_b signal can be activated by Software
- There is a power down counter which gets enabled out of any reset. This counter has a fixed time out period of 16 seconds upon which it will assert the ipp_wdog_b signal

27.2 Watchdog Connectivity

The following Figure shows the way different WDOG on this device needs to be connected to GIC, NVIC, SRC , CSU and the pins.

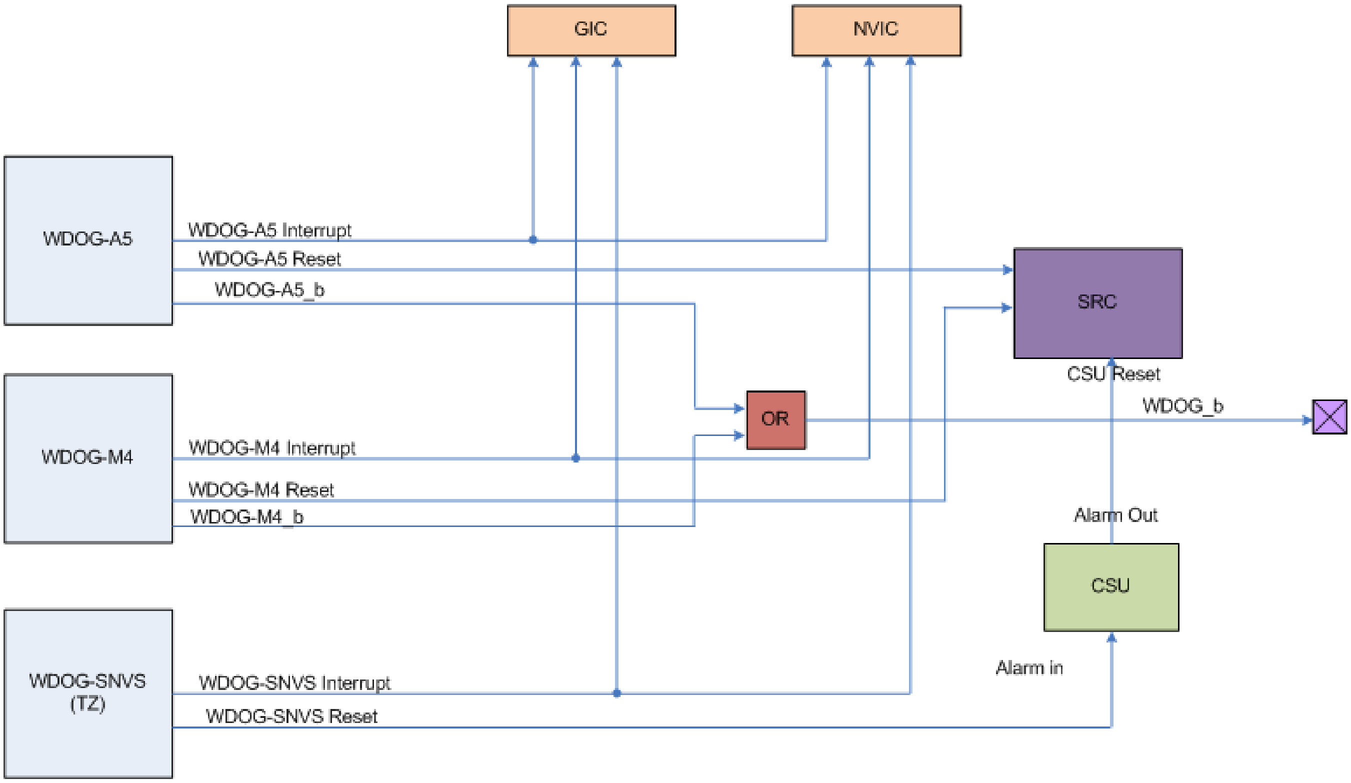

Figure 27-1. WDOG Connectivity

Any WDOG that times out (except WDOG_SNVS) must generate a reset to Reset controller(SRC). This is applicable for both conditions a) where A5 is primary and M4 is secondary b) where M4 is Primary and A5 is secondary.

NOTE

This device does not support a system recovery where A5 only domain or M4 only domain is reset. Either WDOG-A5 or WDOG-M4 generated reset should eventually RESET the system.

Reset generated by the WDOG_SNVS is moderated by CSU.

WDOG_b output to the pins could be optionally used by extenal power management IC to turn off/control the power to the chip.

27.3 WDOG clocking options

WDOG-A5 WDOG-M4 & WDOG-SNVS should supply following clock options

a) 128K IRC

b) 32K Crystal

c) Bus clock (Divided)

Default option MUST be 128 IRC.

27.4 WDOG Debug requirement

1. The CM4 watchdog(WDOG-M4) should freeze if the CM4 enters debug halt mode.
2. The CA5 watchdog(WDOG-A5) should freeze if the CA5 enters debug halt mode.

The above requirements are on top on what is already supported by the IP.

Chapter 28
Wakeup Unit (WKPU)

28.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The WKPU supports 16 external sources that can generate interrupts or wakeup events and 1 external source(s) that can cause non-maskable interrupt request(s) or wakeup event(s). In addition, it combines its wakeup events with those generated from 5 other wakeup sources to supply a single wakeup to the system. The block diagram of the WKPU and its interfaces to other system components is shown below.

NOTE

The signal widths in the following diagram might not depict this device's particular configuration. See the chip configuration chapter for more information.

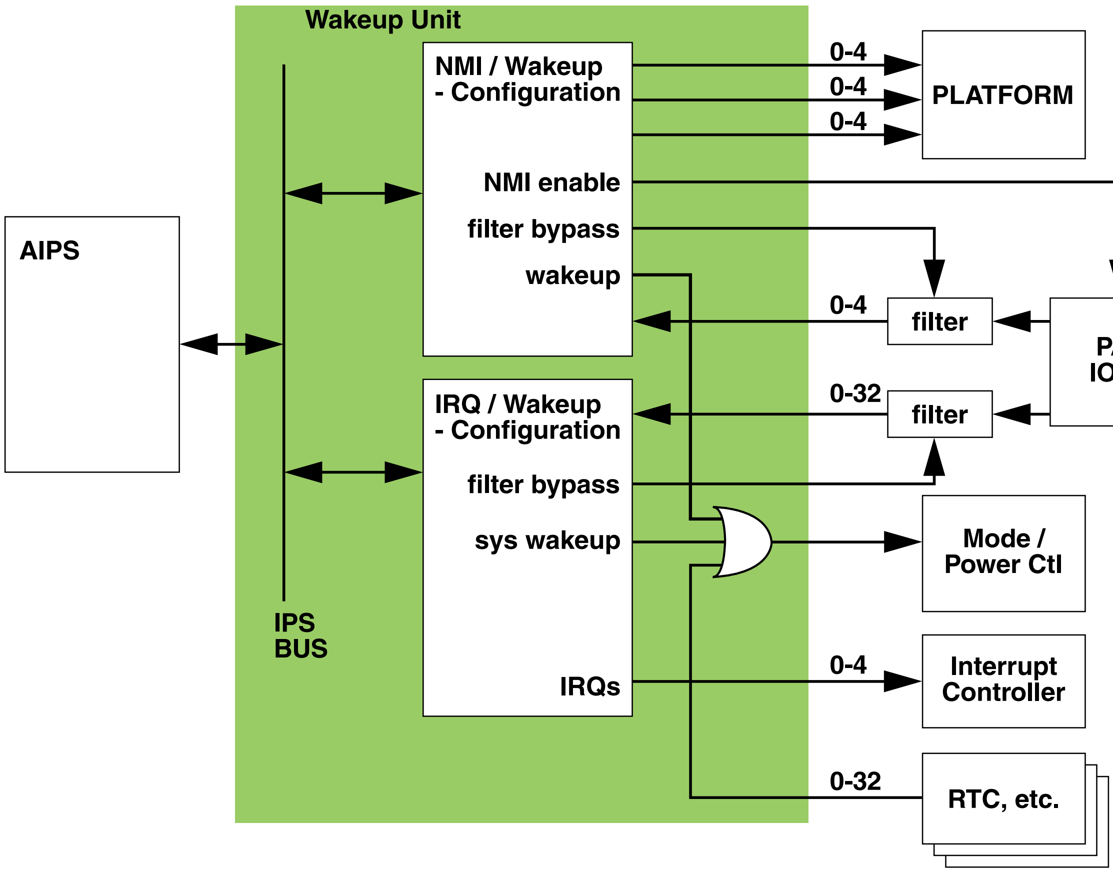

Figure 28-1. WKPU and connected system components

28.2 Features

The WKPU supports these features:

- Non-maskable Interrupt support with:
    - One external NMI source
    - One analog glitch filter
- Independent interrupt destination for each core:
    - Non-maskable interrupt
- Active edge selection control for events to each core
- Configurable system wakeup triggering from NMI source(s)
- External wakeup/interrupt support with:
    - One system interrupt vector for interrupt sources

  - 16 analog glitch filters
  - Independent interrupt mask
  - Edge detection
  - Configurable system wakeup triggering from all interrupt sources
  - Configurable pullup
- On-chip wakeup support:
  - Five wakeup sources
  - Wakeup status mapped to same register as external wakeup/interrupt status

28.3 External signal description

The WKPU has 16 signal inputs that can be used as external interrupt sources in normal run mode or as system wakeup sources in certain power down modes.

The module has 1 signal input(s) that can be used as non-maskable interrupt source(s) in normal run mode or as system wakeup sources in certain power down modes.

28.4 WKPU memory map and registers

This section provides a detailed description of all registers accessible in the WKPU module.

NOTE

Reserved registers will read as 0, writes will have no effect. If supported and enabled by the SoC, a transfer error will be issued when trying to access completely reserved register space.

WKPU memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4006_A000	NMI Status Flag Register (WKPU_NSR)	32	R/W	0000_0000h	28.4.1/1148
4006_A008	NMI Configuration Register (WKPU_NCR)	32	R/W	0000_0000h	28.4.2/1149
4006_A014	Wakeup/Interrupt Status Flag Register (WKPU_WISR)	32	R/W	0000_0000h	28.4.3/1150

Table continues on the next page...

WKPU memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4006_A018	Interrupt Request Enable Register (WKPU_IRER)	32	R/W	0000_0000h	28.4.4/1151
4006_A01C	Wakeup Request Enable Register (WKPU_WRER)	32	R/W	0000_0000h	28.4.5/1152
4006_A028	Wakeup/Interrupt Rising-Edge Event Enable Register (WKPU_WIREER)	32	R/W	0000_0000h	28.4.6/1152
4006_A02C	Wakeup/Interrupt Falling-Edge Event Enable Register (WKPU_WIFEER)	32	R/W	0000_0000h	28.4.7/1153
4006_A030	Wakeup/Interrupt Filter Enable Register (WKPU_WIFER)	32	R/W	0000_0000h	28.4.8/1153
4006_A034	Wakeup/Interrupt Pullup Enable Register (WKPU_WIPUER)	32	R/W	0000_0000h	28.4.9/1154

28.4.1 NMI Status Flag Register (WKPU_NSR)

This register holds the non-maskable interrupt status flags.

NOTE

This register is accessible by 8-, 16-, and 32-bit read/write operations

Address: 4006_A000h base + 0h offset = 4006_A000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	NIF0	NOVF0	0						0		0					
W	w1c	w1c														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

WKPU_NSR field descriptions

Field	Description
31 NIF0	NMI Status Flag 0. This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE0 or NFEE0 set), NIF0 causes an interrupt request.

Table continues on the next page...

WKPU_NSR field descriptions (continued)

Field	Description
	0 No event has occurred on the pad 1 An event as defined by NREE0 and NFEE0 has occurred
30 NOVF0	NMI Overrun Status Flag 0. This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF0 value whenever a NMI event occurs, thereby indicating to the software that a NMI occurred while the last one was not yet serviced. If enabled (NREE0 or NFEE0 set), NOVF0 causes an interrupt request. 0 No overrun has occurred on NMI input 0 1 An overrun has occurred on NMI input 0
29–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–14 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
13–8 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

28.4.2 NMI Configuration Register (WKPU_NCR)

This register holds the configuration bits for the non-maskable interrupt settings.

NOTE

This register is accessible by 8-, 16-, and 32-bit read/write operations

NOTE

Writing a '0' to both NREE[x] and NFEE[x] disables the NMI functionality completely (i.e. no system wakeup or interrupt will be generated on any pad activity)

Address: 4006_A000h base + 8h offset = 4006_A008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

WKPU_NCR field descriptions

Field	Description
31 NLOCK0	NMI Configuration Lock Register 0. Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset or STANDBY0 mode exit. Writing a 0 has no effect.
30–29 NDSS0	NMI Destination Source Select 0. This value is reset on STANDBY0 mode entry . 00 non-maskable interrupt 01 Reserved 10 Reserved 11 Reserved
28 NWRE0	NMI Wakeup Request Enable 0. 0 System wakeup requests from the corresponding NIF0 bit are disabled 1 A set NIF0 bit or set NOVF0 bit causes a system wakeup request
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 NREE0	NMI Rising-edge Events Enable 0. 0 Rising-edge event is disabled 1 Rising-edge event is enabled
25 NFEE0	NMI Falling-edge Events Enable 0. 0 Falling-edge event is disabled 1 Falling-edge event is enabled
24 NFE0	NMI Filter Enable 0. Enable analog glitch filter on the NMI pad input. 0 Filter is disabled 1 Filter is enabled
23–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

28.4.3 Wakeup/Interrupt Status Flag Register (WKPU_WISR)

This register holds the wakeup/interrupt flags.

NOTE

- This register is accessible only by 32-bit read/write operations
- Status bits associated with on-chip wakeup sources are located to the left of the external wakeup/interrupt status bits and are read only. The wakeup for these sources must be configured and cleared at the on-chip wakeup source. Also, the configuration registers for the external interrupts/wakeups do not have corresponding bits.

Address: 4006_A000h base + 14h offset = 4006_A014h

Bit	31–0
R	EIF
W	w1c
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

WKPU_WISR field descriptions

Field	Description
31–0 EIF	External Wakeup/Interrupt Status Flag x. This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (IRER[x]), EIF[x] causes an interrupt request. 0 No event has occurred on the pad 1 An event as defined by WIREER and WIFEER has occurred

28.4.4 Interrupt Request Enable Register (WKPU_IRER)

This register is used to enable the interrupt messaging from the wakeup/interrupt pads to the interrupt controller.

NOTE

This register is accessible only by 32-bit read/write operations

Address: 4006_A000h base + 18h offset = 4006_A018h

Bit	31–0
R W	EIRE
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

WKPU_IRER field descriptions

Field	Description
31–0 EIRE	External Interrupt Request Enable x. 0 Interrupt requests from the corresponding EIF[x] bit are disabled 1 A set EIF[x] bit causes an interrupt request

28.4.5 Wakeup Request Enable Register (WKPU_WRER)

This register is used to enable the system wakeup messaging from the wakeup/interrupt pads to the mode entry and power control modules.

NOTE

This register is accessible only by 32-bit read/write operations

If a pin is disabled through this register, the corresponding bits in the WIFEER and WIREER registers must be written to 0 to ensure that the pin does not respond to any change.

Address: 4006_A000h base + 1Ch offset = 4006_A01Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	WRE																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

WKPU_WRER field descriptions

Field	Description
31–0 WRE	External Wakeup Request Enable x. 0 System wakeup requests from the corresponding EIF[x] bit are disabled 1 A set EIF[x] bit causes a system wakeup request

28.4.6 Wakeup/Interrupt Rising-Edge Event Enable Register (WKPU_WIREER)

This register is used to enable rising-edge triggered events on the corresponding wakeup/ interrupt pads.

NOTE

This register is accessible only by 32-bit read/write operations

Address: 4006_A000h base + 28h offset = 4006_A028h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	IREE																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

WKPU_WIREER field descriptions

Field	Description
31–0 IREE	External Interrupt Rising-edge Events Enable x. 0 Rising-edge event is disabled 1 Rising-edge event is enabled

28.4.7 Wakeup/Interrupt Falling-Edge Event Enable Register (WKPU_WIFEER)

This register is used to enable falling-edge triggered events on the corresponding wakeup/ interrupt pads.

NOTE

This register is accessible only by 32-bit read/write operations

Address: 4006_A000h base + 2Ch offset = 4006_A02Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	IFEEx																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

WKPU_WIFEER field descriptions

Field	Description
31–0 IFEEx	External Interrupt Falling-edge Events Enable x. 1 Falling-edge event is enabled 0 Falling-edge event is disabled

28.4.8 Wakeup/Interrupt Filter Enable Register (WKPU_WIFER)

This register is used to enable an analog filter on the corresponding interrupt pads to filter out glitches on the inputs. The number of wakeups/interrupts supporting this feature is SoC dependent and can be configured to be between 1 and 32.

NOTE

This register is accessible only by 32-bit read/write operations

Address: 4006_A000h base + 30h offset = 4006_A030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	IFE																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

WKPU_WIFER field descriptions

Field	Description
31–0 IFE	External Interrupt Filter Enable x. Enable analog glitch filter on the external interrupt pad input. 0 Filter is disabled 1 Filter is enabled

28.4.9 Wakeup/Interrupt Pullup Enable Register (WKPU_WIPUER)

This register is used to enable a pullup on the corresponding interrupt pads to pull an unconnected wakeup/interrupt input to a value of '1'.

NOTE

This register is accessible only by 32-bit read/write operations

Address: 4006_A000h base + 34h offset = 4006_A034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	IPUE																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

WKPU_WIPUER field descriptions

Field	Description
31–0 IPUE	External Inpterrupt Pullup Enable x. 0 Pullup is disabled 1 Pullup is enabled

28.5 Functional description

This section provides a functional description of the WKPU.

28.5.1 Non-maskable interrupts

The WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event.

Each NMI passes through a bypassable analog glitch filter.

NOTE

Glitch filter control and pad configuration should be done while the NMI is disabled in order to avoid erroneous triggering by glitches caused by the configuration process itself.

NOTE

The figure below represents a generic configuration and might not represent this particular device's configuration. See the chip-specific information for details on this chip's WKPU.

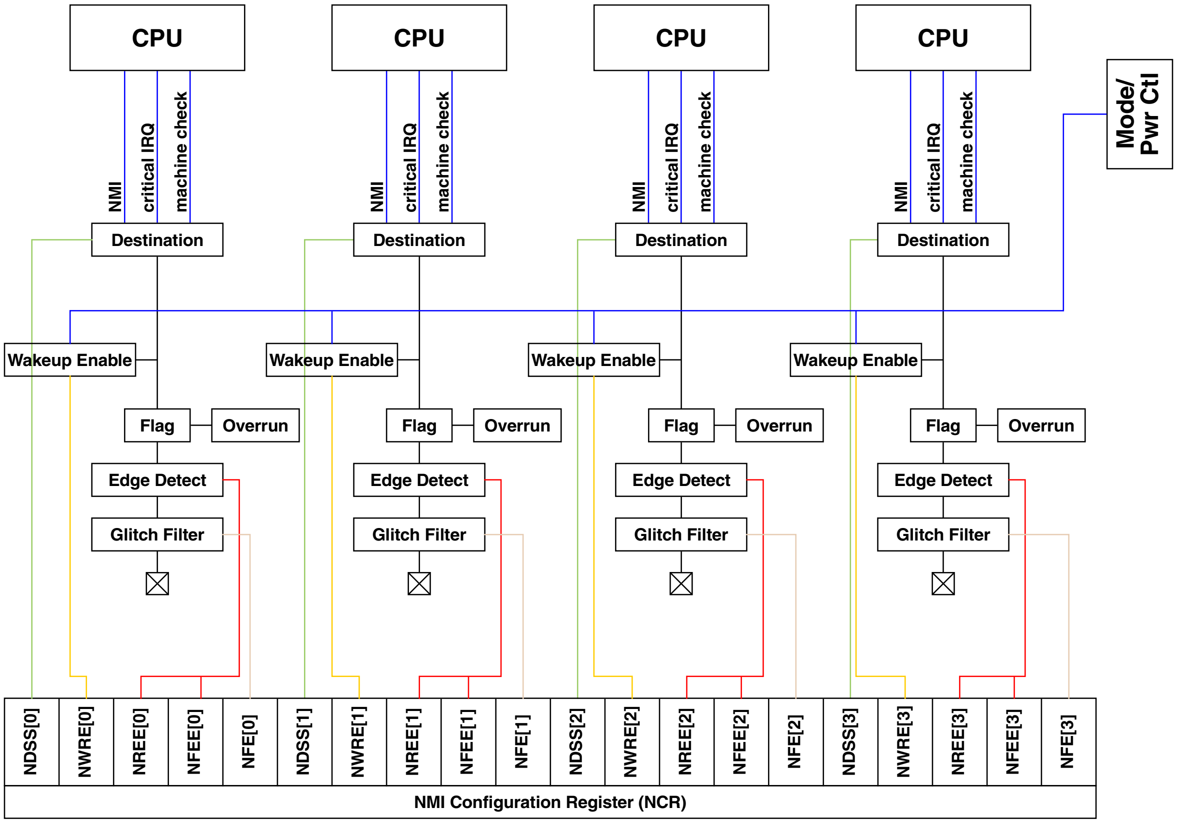

Figure 28-11. NMI pad diagram

28.5.1.1 NMI management

Each NMI can be enabled or disabled independently. This can be performed using the single NCR register laid out to contain all configuration bits for a given NMI in a single byte (see NMI Configuration Register (WKPU_NCR)). A pad defined as an NMI can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active. A setting of having both edge events disabled results in no interrupt being detected and should not be configured.

The active NMI edge is controlled by the user through the configuration of the NREE and NFEE bits.

Note

> After reset, NREE and NFEE are set to '0', therefore the NMI functionality is disabled after reset and must be enabled explicitly by software.

Once a pad's NMI functionality has been enabled, the pad cannot be reconfigured in the IOMUX to override or disable the NMI.

The NMI destination interrupt is controlled by the user through the configuration of the NDSS bits. See NMI Configuration Register (WKPU_NCR) for details.

Each NMI supports a status flag and an overrun flag which are located in the NSR register (see NMI Status Flag Register (WKPU_NSR)). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register. The status flag is set whenever an NMI event is detected. The overrun flag is set whenever an NMI event is detected and the status flag is set (i.e. has not yet been cleared).

Note

> The overrun flag is cleared by writing a '1' to the appropriate overrun bit in the NSR register. If the status bit is cleared and the overrun bit is still set, the pending interrupt will not be cleared.
>
> During an NMI ISR, on wakeup of the SoC from an NMI, any writes to ECC-protected memory must have the correct ECC.

28.5.2 External wakeups/interrupts

The WKPU supports 1 interrupt vector(s) to the interrupt controller of the SoC. Each interrupt vector can support up to the number of external interrupt sources from the device pads with the total across all vectors being equal to the number of external interrupt sources. Each external interrupt sources is assigned to exactly one interrupt vector. The interrupt vector assignment is sequential so that one interrupt vector is for external interrupt sources 0 through N-1, the next is for N through N+M-1, and so forth.

Refer to the following figure for an overview of the external interrupt implementation for the example of four interrupt vectors with eight external interrupt sources each.

NOTE

The figure below shows a generic representation of the WKPU. See the chip configuration chapter for details on how this device's configuration might differ from this figure.

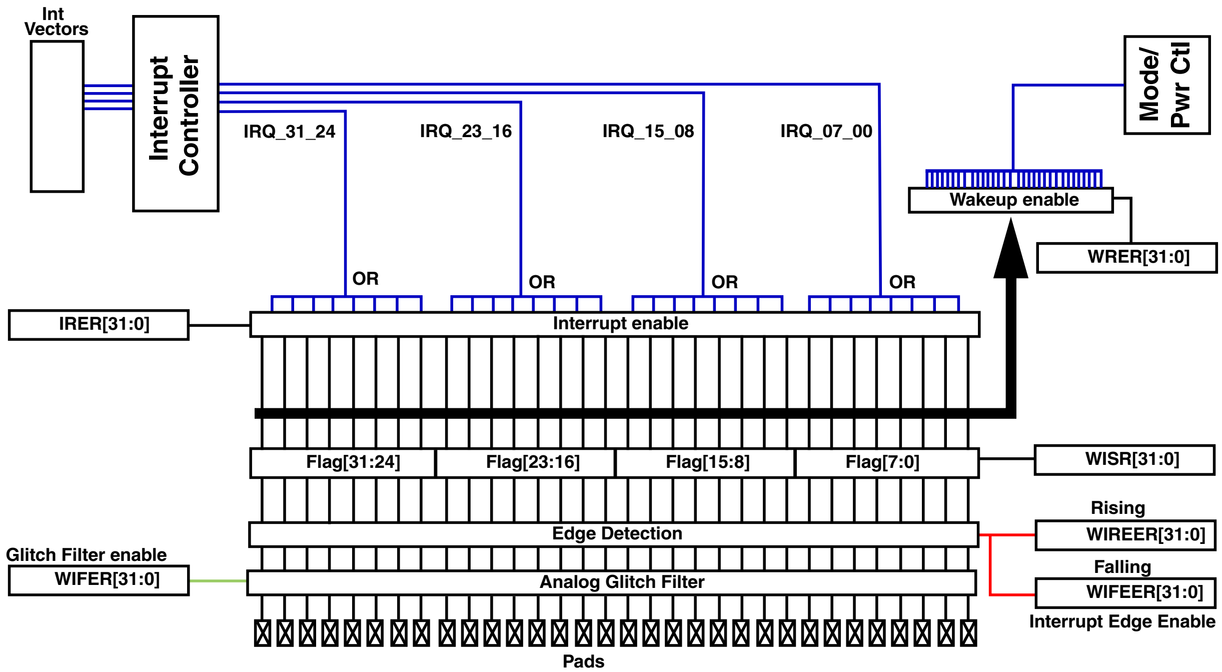

Figure 28-12. External interrupt pad diagram

All of the external interrupt pads within a single group have equal priority. It is the responsibility of the user software to search through the group of sources in the most appropriate way for their application.

The priority of the vectors used by the external interrupt pads is fixed based on the platform and the interrupt controller and its priority levels, but the allocation of pads to each group of interrupts can be independently configured by the SoC.

External interrupt lines have a digital glitch filters applied to them.

28.5.2.1 External interrupt management

Each interrupt can be enabled or disabled independently. This can be performed using a single rolled up register (Interrupt Request Enable Register (WKPU_IRER)). A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active.

Note

> Writing a '0' to both IREE[x] and IFEE[x] disables the external interrupt functionality for that pad completely (i.e. no system wakeup or interrupt will be generated on any activity on that pad)!

The active IRQ edge is controlled by the users through the configuration of the registers WIREER and WIFEER.

Each external interrupt supports an individual flag which is held in the flag register (WISR). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

28.5.3 On-chip wakeups

The WKPU supports 5 on-chip wakeup sources. It combines the on-chip wakeups with the external ones to generate a single wakeup to the system.

28.5.3.1 On-chip wakeup management

In order to allow software to determine the wakeup source at one location, on-chip wakeups are reported along with external wakeups in the WISR register (see Wakeup/ Interrupt Status Flag Register (WKPU_WISR) for details). Enabling and clearing of these wakeups are done via the on-chip wakeup source's own registers.

28.6 Initialization Information

This section discusses initialization for the following features:

- Glitch Filter and Pad Configuration
- Non-maskable interrupt initialization
- Reset Request

28.6.1 Glitch Filter and Pad Configuration

Glitch filter control and pad configuration should be performed while the NMI is disabled in order to avoid erroneous triggering by glitches caused by the configuration process itself.

When enabling the glitch filter, do not enable the rising-/falling-edge events bits, i.e., the NREE, NFEE, RREE, and RFEE, bits in the same register write.

28.6.2 Non-Maskable Interrupts

When an NMI interrupt pin is first enabled, it is possible to get a false interrupt flag. To prevent a false interrupt request during pin interrupt initialization the user must do the following:

1. Mask interrupts by clearing NSR[NIF*n*] and NSR[NOVF*n*].
2. Clear NCR[NFEE*n*] and NCR[NREE*n*], preferably by writing 0 to all bits in the register.
3. Configure the analog glitch filter using NCR[NFE0].
4. Configure the appropriate SIUL2_MSCR register for the desired NMI interrupt pin(s) as follows:
    - Clear the ODC bits to disable output.
    - Set the IBE bit to enable the pin's input buffer.
    - If the internal weak pull-up/pull-down is used, configure the appropriate WPUE and WPDE bits.

    NOTE

    NMI interrupt pins should never be configured as outputs, i.e., MSCR[ODC] bits are not zeros, when external interrupt inputs are desired since false interrupts could be detected (such as from a GPIO configuration).

5. Write appropriate bit values to the NCR register to configure:
    - NMI source (NDSS*n*).
    - Wakeup request (NWRE*n*).

- Glitch filter (NFE0)
- Rising/falling edge events enable (NFEE*n* and NREE*n*).
- NMI configuration lock (NLOCK*n*).

28.6.3 Reset Request

When an NMI reset request pin is first enabled, it is possible to get a false reset request. To prevent a false reset request during pin reset request initialization, the user must do the following:

1. Mask reset requests by clearing NSR[RIF] and NSR[ROVF].
2. Clear NCR[RFEE] and NCR[RREE], preferably by writing 0 to all bits in this register.
3. Configure the analog glitch filter, as desired, using NCR[NFE0].
4. Configure the appropriate SIUL2_MSCR register for the NMI interrupt pin(s) as follows:
    - Clear the ODC bits to disable output.
    - Set the IBE bit to enable the pin's input buffer.
    - If the internal weak pull-up/pull-down is used, configure the appropriate WPUE and WPDE bits.

NOTE

NMI reset request pins should never be configured as outputs (i.e., MSCR[ODC] bits are not zeros) when external reset request inputs are desired since false reset requests could be detected (e.g., from a GPIO configuration).

5. Write appropriate bit values to the NCR register to configure:
    - Reset destination source (RDSS]).
    - Reset wakeup request (RWRE).
    - Glitch filter (NFE0)

- Rising/falling edge events enable (RFEE and RREE).
- Reset configuration lock (RLOCK).

Chapter 29
Local Memory Controller

29.1 Introduction

The Local Memory Controller provides the ARM®Cortex-M4™ processor with tightly-coupled processor-local memories and bus paths to all slave memory spaces.

29.1.1 Block Diagram

The Cortex-M4 processor has a modified 32-bit Harvard bus architecture. Using a 32-bit address space, low-order addresses (0x0000_0000 through 0x1FFF_FFFF) use the Processor Code (PC) bus, and high-order addresses (0x2000_0000 through 0xFFFF_FFFF) use the Processor System (PS) bus. As the bus names imply, normal operation has code accesses on the PC bus and data accesses on the PS bus.

This device has been augmented with tightly-coupled memories for the PC and PS buses. The memories include RAMs and caches. These local memories provide zero wait state access to RAM and cacheable address spaces.

The local memory controller includes four memory controllers and their attached memories:

- SRAM lower (SRAM_L) controller via the PC bus
- SRAM upper (SRAM_U) controller via the PS bus
- Cache memory controller via the PC bus
- Cache memory controller via the PS bus

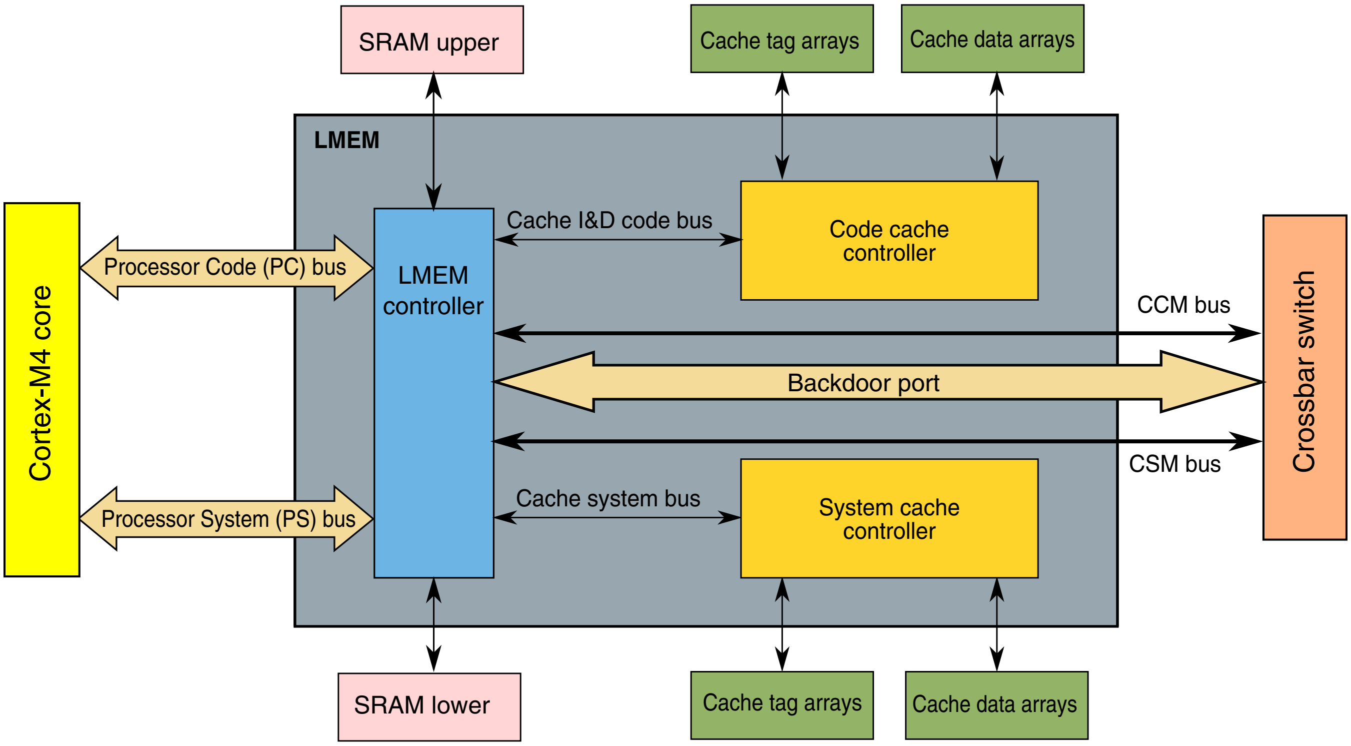

Figure 29-1. Local memory controller block diagram

NOTE

The SRAM and cache controllers reside within the LMEM, but the single-port synchronous RAM arrays used by these controllers are external.

The LMEM contains address decode logic for the PC and PS buses. This logic routes the core's accesses to the various system resources. The address spaces are device-specific and are specified in the device's Chip Configuration chapter.

The CM4 core address space is decoded as follows:

Table 29-1. Address Space Decode

Address Range	Core/Slave Bus[1]	Slave Target, XBAR Port	Cache Mode at reset
0x0000_0000 → 0x07FF_FFFF	PC/CCM	Boot Rom (S0A)	cacheable write-through
0x0800_0000 → 0x0FFF_FFFF	PC/CCM	DDR code alias (S8)	cacheable write-through
0x1000_0000 → 0x17FF_FFFF	PC/CCM	QuadSPI0 alias (S2)	cacheable write-through
0x1800_0000 → 0x1EFF_FFFF	PC/CCM	FlexBus code alias (S0B)	cacheable write-through
0x1F00_0000→0x1F7F_FFFF	PC/CCM	OCRAM code alias (S3/S4/S5)	cacheable write-through
0x1F80_0000→0x1FFF_FFFF	PC/---	CM4_TCML Frontdoor	non-cacheable
0x2000_0000 → 0x2FFF_FFFF	PS/CSM	QuadSPI0 (S2)	cacheable write-back

Table continues on the next page...

Table 29-1. Address Space Decode (continued)

Address Range	Core/Slave Bus[1]	Slave Target, XBAR Port	Cache Mode at reset
0x3000_0000 → 0x3EFF_FFFF	PS/CSM	FlexBus (S0B)	cacheable write-back
0x3F00_0000 → 0x3F7F_FFFF	PS/CSM	OCRAM (S3/S4/S5)	cacheable write-back
0x3F80_0000 → 0x3FFF_FFFF	PS/---	CM4_TCMU Frontdoor	non-cacheable
0x4000_0000 → 0x4006_FFFF	PS/CSM	IPS0 Peripherals (S0C)	non-cacheable
0x4007_0000 → 0x4007_FFFF	PS/CSM	Secure RAM (S6)	non-cacheable
0x4008_0000 → 0x400F_EFFF	PS/CSM	IPS1 Peripherals (S1C)	non-cacheable
0x400F_0000 → 0x400F_FFFF	PS/CSM	RGPIO (S1A)	non-cacheable
0x4010_0000 → 0x4FFF_FFFF	PS/CSM	NOT USED	–
0x5000_0000 → 0x5FFF_FFFF	PS/CSM	QuadSPI1 (S7A)	cacheable
0x6000_0000 → 0x77FF_FFFF	PS/CSM	NOT USED	–
0x7800_0000→0x79FF_FFFF	PS/CSM	RLE (S7B)	cacheable write-through
0x7A00_0000→0x7BFF_FFFF	PS/CSM	QS1 RxBuf (S7A)	cacheable write-through
0x7C00_0000→0x7DFF_FFFF	PS/CSM	QS0 RxBuf (S2)	cacheable write-through
0x7E00_0000→0x7FFF_FFFF	PS/CSM	altGFXRAM (S5)	cacheable write-through
0x8000_0000→0xDFFF_FFFF	PS/CSM	DDR (S8)	cacheable write-back
0xE000_0000→0xE00F_FFFF	2	CM4 PPB	–

1. All references are routed to the core's Private Peripheral Bus (PPB) and never appear on the PS/CSM buses.
2. All references are routed to the core's Private Peripheral Bus (PPB) and never appear on the PS/CSM buses.

29.1.2 Cache features

A cache is a block of high-speed memory locations containing address information (commonly known as a tag) and the associated data. The purpose is to decrease the average time of a memory access. Caches operate on two principles of locality:

- Spatial locality — An access to one location is likely to be followed by accesses from adjacent locations (for example, sequential instruction execution or usage of a data structure).
- Temporal locality — An access to an area of memory is likely to be repeated within a short time period (for example, execution of a code loop).

To minimize the quantity of control information stored, the spatial locality property is used to group several locations together under the same tag. This logical block is commonly known as a cache line.

When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a cache hit, and other accesses are called cache misses.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the processor wants to access a cacheable location, the cache is checked. If the access is a cache hit, the access occurs immediately. Otherwise, a location is allocated and the cache line is loaded from memory. Different cache topologies and access policies are possible. However, they must comply with the memory coherency model of the underlying architecture.

Caches introduce a number of potential problems, mainly because of:

- memory accesses occurring at times other than when the programmer would normally expect them,
- the existence of multiple physical locations where a data item can be held.

The local memory controller supports three modes of operation:

1. Write-through — access to address spaces with this cache mode are cacheable.
    - A read miss on the input bus causes a line read on the output busof a 32-byte-aligned memory address containing the desired address. This miss data is loaded into the cache and is marked as valid and not modified.
    - A write-through read hit to a valid cache location returns data from the cache with no output bus access.
    - A write-through write miss bypasses the cache and writes to the output bus (no allocate on write miss policy for write-through mode spaces).
    - A write-through write hit updates the cache hit data and writes to the output bus.
2. Write-back — access to address spaces with this cache mode are cacheable.
    - A write-back read miss on the input bus will cause a line read on the output bus of a 32-byte-aligned memory address containing the desired address. This miss data is loaded into the cache and marked as valid and not modified.
    - A write-back read hit to a valid cache location will return data from the cache with no output bus access.
    - A write-back write miss will do a "read-to-write" (allocate on write miss policy for write-back mode spaces). A line read on the output bus of a 16 byte aligned memory address containing the desired write address is performed. This miss data is loaded into the cache and marked as valid and modified; and the write data will then update the appropriate cache data locations.
3. Non-cacheable — access to address spaces with this cache mode are not cacheable. These accesses bypass the cache and access the output bus.

29.2 Memory Map/Register Definition

The cache programmer's model provides a variety of registers for configuring and controlling the cache, as well as indirect access paths to all cache tag and data storage.

LMEM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
E008_2000	Cache control register (LMEM_PCCCR)	32	R/W	0000_0000h	29.2.1/1167
E008_2004	Cache line control register (LMEM_PCCLCR)	32	R/W	0000_0000h	29.2.2/1168
E008_2008	Cache search address register (LMEM_PCCSAR)	32	R/W	0000_0000h	29.2.3/1171
E008_200C	Cache read/write value register (LMEM_PCCCVR)	32	R/W	0000_0000h	29.2.4/1172
E008_2800	Cache control register (LMEM_PSCCR)	32	R/W	0000_0000h	29.2.5/1172
E008_2804	Cache line control register (LMEM_PSCLCR)	32	R/W	0000_0000h	29.2.6/1174
E008_2808	Cache search address register (LMEM_PSCSAR)	32	R/W	0000_0000h	29.2.7/1176
E008_280C	Cache read/write value register (LMEM_PSCCVR)	32	R/W	0000_0000h	29.2.8/1177

29.2.1 Cache control register (LMEM_PCCCR)

Address: E008_2000h base + 0h offset = E008_2000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

LMEM_PCCCR field descriptions

Field	Description
31 GO	Initiate Cache Command Setting this bit initiates the cache command indicated by bits 27-24. Reading this bit indicates if a command is active **NOTE:** This bit stays set until the command completes. Writing zero has no effect. 0 Write: no effect. Read: no cache command active. 1 Write: initiate command indicated by bits 27-24. Read: cache command active.
30–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 PUSHW1	Push Way 1

Table continues on the next page...

LMEM_PCCCR field descriptions (continued)

Field	Description
	0 No operation 1 When setting the GO bit, push all modified lines in way 1
26 INVW1	Invalidate Way 1 **NOTE:** If the PUSHW1 and INVW1 bits are set, then after setting the GO bit, push all modified lines in way 1 and invalidate all lines in way 1 (clear way 1). 0 No operation 1 When setting the GO bit, invalidate all lines in way 1
25 PUSHW0	Push Way 0 0 No operation 1 When setting the GO bit, push all modified lines in way 0
24 INVW0	Invalidate Way 0 **NOTE:** If the PUSHW0 and INVW0 bits are set, then after setting the GO bit, push all modified lines in way 0 and invalidate all lines in way 0 (clear way 0). 0 No operation 1 When setting the GO bit, invalidate all lines in way 0.
23–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3 PCCR3	Forces no allocation on cache misses (must also have ACCR2 asserted)
2 PCCR2	Forces all cacheable spaces to write through
1 ENWRBUF	Enable Write Buffer 0 Write buffer disabled 1 Write buffer enabled
0 ENCACHE	Cache enable 0 Cache disabled 1 Cache enabled

29.2.2 Cache line control register (LMEM_PCCLCR)

This register defines specific line-sized cache operations to be performed using a specific cache line address or a physical address.

If a physical address is specified, both ways of the cache are searched, and the command is only performed on the way which hits.

Address: E008_2000h base + 4h offset = E008_2004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0				LACC	LADSEL	LCMD		0	LCWAY	LCIMB	LCIVB	0			TDSEL

LMEM_PCCLCR field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27 LACC	Line access type 0 Read 1 Write
26 LADSEL	Line Address Select When using the cache address, the way must also be specified in CLCR[WSEL]. When using the physical address, both ways are searched and the command is performed only if a hit. 0 Cache address 1 Physical address
25–24 LCMD	Line Command 00 Search and read or write 01 Invalidate 10 Push 11 Clear

Table continues on the next page...

LMEM_PCCLCR field descriptions (continued)

Field	Description
23 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
22 LCWAY	Line Command Way Indicates the way used by the line command.
21 LCIMB	Line Command Initial Modified Bit If command used cache address and way, then this bit shows the initial state of the modified bit If command used physical address and a hit, then this bit shows the initial state of the modified bit. If a miss, this bit reads zero.
20 LCIVB	Line Command Initial Valid Bit If command used cache address and way, then this bit shows the initial state of the valid bit If command used physical address and a hit, then this bit shows the initial state of the valid bit. If a miss, this bit reads zero.
19–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 TDSEL	Tag/Data Select Selects tag or data for search and read or write commands. 0 Data 1 Tag
15 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
14 WSEL	Way select Selects the way for line commands. 0 Way 0 1 Way 1
13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–2 CACHEADDR	Cache address CLCR[11:4] bits are used to access the tag arrays CLCR[11:2] bits are used to access the data arrays
1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 LGO	Initiate Cache Line Command Setting this bit initiates the cache line command indicated by bits 27-24. Reading this bit indicates if a line command is active **NOTE:** This bit stays set until the command completes. Writing zero has no effect. **NOTE:** This bit is shared with CSAR[LGO] 0 Write: no effect. Read: no line command active. 1 Write: initiate line command indicated by bits 27-24. Read: line command active.

29.2.3 Cache search address register (LMEM_PCCSAR)

The CSAR register is used to define the explicit cache address or the physical address for line-sized commands specified in the CLCR[LADSEL] bit.

Address: E008_2000h base + 8h offset = E008_2008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	PHYADDR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Field	Description
31–0 DATA	Cache read/write Data For tag search, read or write: • CCVR[31:12] bits are used for tag array R/W value • CCVR[11:4] bits are used for tag set address on reads; unused on writes • CCVR[3:2] bits are reserved For data search, read or write: • CCVR[31:0] bits are used for data array R/W value

29.3 Functional Description

29.3.1 LMEM Function

The Local Memory Controller receives the following requests:

- Core master bus requests on the Processor Code (PC) bus,
- Core master bus requests on the Processor Space (PS) bus, and
- SRAM controller requests from all other bus masters on the backdoor port.

The Local Memory Controller address decode logic routes these accesses and also provides any crossbar switch slave target logic. Finally, the Local Memory controller provides the needed MPU connections for checking all SRAM controller and cacheable accesses.

The programming model for the Code and System Caches is accessed via the core's Private Peripheral Bus (PPB).

29.3.1.1 Processor Code accesses

Processor Code accesses are routed to the SRAM_L if they are mapped to that space. All other PC accesses are routed to the Code Cache Memory Controller. This controller then processes the cacheable accesses as needed, while bypassing the non-cacheable, cache write-through, cache miss, and cache maintenance accesses to the CCM bus and the crossbar switch using the Master0 port.

29.3.1.2 Processor Space accesses

Processor Space accesses are routed to the SRAM_U if they are mapped to that space. All other PS accesses are routed to the PS Cache Memory Controller. This controller then processes the cacheable accesses as needed, while bypassing the non-cacheable, cache write-through, cache miss, and cache maintenance accesses to the CCM bus and the crossbar switch using the Master1 port.

29.3.1.3 Backdoor port accesses

All LMEM backdoor port accesses are for the SRAM controller. These accesses go to the SRAM_L or the SRAM_U depending on their specific address.

29.3.2 SRAM Function

29.3.2.1 SRAM Configuration

The figure below shows how the SRAM controller is configured.

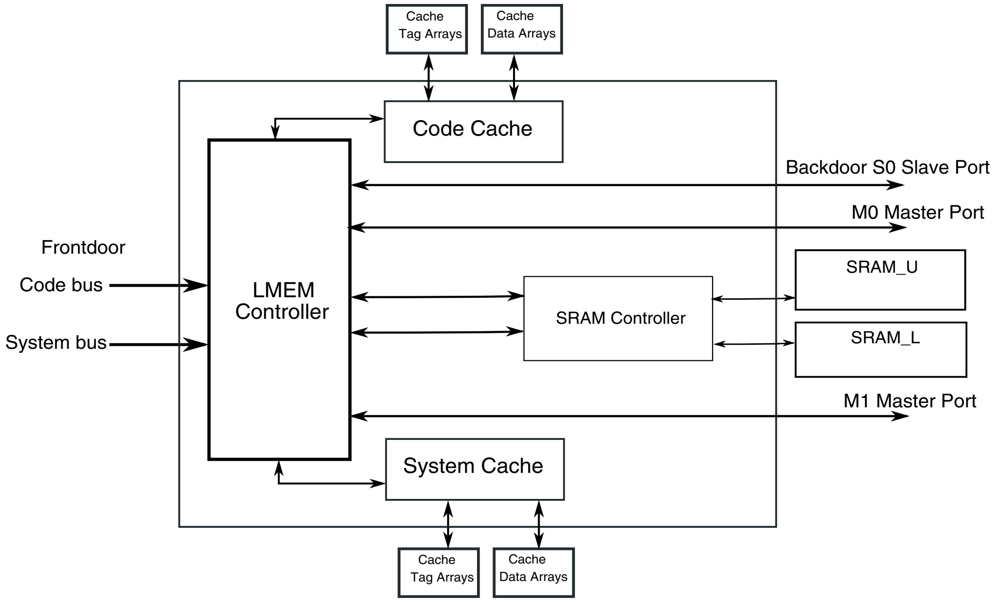

Figure 29-10. SRAM Configuration

29.3.2.2 SRAM Arrays

The on-chip SRAM is split into two logical arrays, SRAM_L and SRAM_U.

From equal-sized memories, valid address ranges for SRAM_L and SRAM_U are then defined as:

- SRAM_L = 0x1F80_0000 - (0x1F80_0000 + SRAM_size/2)
- SRAM_U = 0x3F80_0000 - (0x3F80_0000 + SRAM_size/2)

29.3.2.3 SRAM accesses

The SRAM is split into two logical arrays that are 64-bits wide:

- SRAM_L — Accessible by the code bus of the Cortex-M4 core and by the backdoor port.
- SRAM_U — Accessible by the system bus of the Cortex-M4 core and by the backdoor port.

The backdoor port makes the SRAM accessible to the non-core bus masters (such as DMA).

Figure 29-11 illustrates the SRAM accesses within the device.

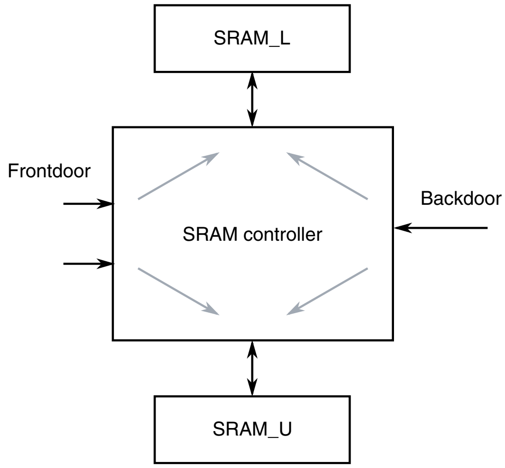

Figure 29-11. SRAM access diagram

The following simultaneous accesses can be made to different logical halves of the SRAM:

- Core code and core system
- Core code and non-core master
- Core system and non-core master

NOTE

Two non-core masters cannot access SRAM simultaneously. The required arbitration and serialization is provided by the crossbar switch. The SRAM_{L,U} arbitration is controlled by the SRAM controller based on the configuration bits in the MCM module.

29.3.3 Cache Function

The caches on this device are structured as follows. Both caches have a 2-way set-associative cache structure with a total size of 32 KBytes. The caches have a 32-bit address, 64-bit data paths and a 32-byte line size. The cache tags and data storage use single-port, synchronous RAMs.

For these 16-KByte caches, each cache TAG function uses two 256 x 22-bit RAM arrays and the cache DATA function uses two 1024 x 32-bit RAM arrays. The cache TAG entries store 20 bits of upper address as well as a modified and valid bit per cache line. The cache DATA entries store eight byes of code or data.

All normal cache accesses use physical addresses. This leads to the following cache address use:

CACHE - 16 KByte size = (256 sets) x (32-byte lines) x (2-way set associative)

TAG:

- address[31:13] used in tag for compare (hit) logic
- address[12:5] used to select 1 of 256 sets
- address[3:0] not used

DATA

- address[31:13] not used
- address[12:5] used to select one of 256 sets
- address[4:2] used to select one of eight 32-bit words within a set
- address[1:0] used to select the byte within the 32-bit word

29.3.4 Cache Control

The Code and System Caches are disabled at reset. Cache tag and data arrays are not cleared at reset. Therefore, to enable the caches, cache commands must be done to clear and initialize the required tag array bits and to configure and enable the caches.

29.3.4.1 Cache set commands

The cache set commands may operate on:

- all of way 0,
- all of way 1, or
- all of both ways (complete cache).

Cache set commands are initiated using the upper bits in the CCR register. Cache set commands perform their operation on the cache independent of the cache enable bit, CCR[ENCACHE].

A cache set command is initiated by setting the CCR[GO] bit. This bit also acts as a busy bit for set commands. It stays set while the command is active and is cleared by the hardware when the set command completes.

Supported cache set commands are given in Table 29-11. Set commands work as follows:

- Invalidate – Unconditionally clear valid and modify bits of a cache entry.
- Push – Push a cache entry if it is valid and modified, then clear the modify bit. If entry not valid or not modified, leave as is.
- Clear – Push a cache entry if it is valid and modified, then clear the valid and modify bits. If entry not valid or not modified, clear the valid bit.

Table 29-11. Cache Set Commands

CCR[27:24]				Command
PUSH W1	INVW1	PUSH W0	INVW0	
0	0	0	0	NOP
0	0	0	1	Invalidate all way 0
0	0	1	0	Push all way 0
0	0	1	1	Clear all way 0
0	1	0	0	Invalidate all way 1
0	1	0	1	Invalidate all way 1; invalidate all way 0 (invalidate cache)
0	1	1	0	Invalidate all way 1; push all way 0
0	1	1	1	Invalidate all way 1; clear all way 0
1	0	0	0	Push all way 1
1	0	0	1	Push all way 1; invalidate all way 0
1	0	1	0	Push all way 1; push all way 0 (push cache)
1	0	1	1	Push all way 1; clear all way 0
1	1	0	0	Clear all way 1
1	1	0	1	Clear all way 1; invalidate all way 0
1	1	1	0	Clear all way 1; push all way 0
1	1	1	1	Clear all way 1; clear all way 0 (clear cache)

After a reset, complete an invalidate cache command before using the cache. It is possible to combine the cache invalidate command with the cache enable. That is, setting CCR to 0x8500_0003 will invalidate the cache and enable the cache and write buffer.

29.3.4.2 Cache line commands

Cache line commands operate on a single line in the cache at a time. Cache line commands can be performed using a physical or cache address.

- A cache address consists of a set address and a way select. The line command acts on the specified cache line.
- Cache line commands with physical addresses first search both ways of the cache set specified by bits [11:4] of the physical address. If they hit, the commands perform their action on the hit way.

Cache line commands are specified using the upper bits in the CLCR register. Cache line commands perform their operation on the cache independent of the cache enable bit (CCR[ENCACHE]). Using a cache address, the command can be completely specified using the CLCR register. Using a physical address, the command must also use the CSAR register to specify the physical address.

A line cache command is initiated by setting the line command go bit (CLCR[LGO] or CSAR[LGO]). This bit also acts a a busy bit for line commands. It stays set while the command is active and is cleared by the hardware when the command completes.

The CLCR[27:24] bits select the line command as follows:

Table 29-12. Cache Line Commands

CLCR[27:24]			Command
LACC	LADSEL	LCMD	
0	0	00	Search by cache address and way
0	0	01	Invalidate by cache address and way
0	0	10	Push by cache address and way
0	0	11	Clear by cache address and way
0	1	00	Search by physical address
0	1	01	Invalidate by physical address
0	1	10	Push by physical address
0	1	11	Clear by physical address
1	0	00	Write by cache address and way
1	0	01	Reserved, NOP
1	0	10	Reserved, NOP
1	0	11	Reserved, NOP
1	1	*xx*	Reserved, NOP

29.3.4.2.1 Executing a series of line commands using cache addresses

A series of line commands with incremental cache addresses can be performed by just writing to the CLCR.

- Place the command in CLCR[27:24],
- Set the way (CLCR[WSEL]) and tag/data (CLCR[TDSEL]) controls as needed,
- Place the cache address in CLCR[CACHEADDR], and
- Set the line command go bit (CLCR[LGO]).

When one line command completes, initiate the next command by following these steps:

- Increment the cache address (at bit 2 to step through data or at bit 4 to step through lines), and
- Set the line command go bit (CLCR[LGO]).

29.3.4.2.2 Executing a series of line commands using physical addresses

Perform a series of line commands with incremental physical addresses using the following steps:

- Write to the CLCR.
  - Place the command in CLCR[27:24]
  - Set the tag/data (CLCR[TDSEL]) control
- Place the physical address in CSAR[PHYADDR] and set the line command go bit (CSAR[LGO]).

When one line command completes, initiate the next command by following these steps:

- Increment the physical address (at bit 2 to step through data or at bit 4 to step through lines), and
- Set the line command go bit (CSAR[LGO]).

The line command go bit is shared between the CLCR and CSAR registers, so that the above steps can be completed in a single write to the CSAR register.

29.3.4.2.3 Line command results

At completion of a line command, the CLCR register contains information on the initial state of the line targeted by the command. For line commands with cache addresses, this information is read before the line command action is performed from the targeted cache line. For line commands with physical addresses, this information is read on a hit before the line command action is performed from the hit cache line or has initial valid bit cleared if the command misses. In general, if the valid indicator (CLCR[LCIVB] is cleared, the targeted line was invalid at the start of the line command and no line operation was performed.

Table 29-13. Line command results

CLCR[22:20]			For cache address commands	For physical address commands
LCWAY	LCIMB	LCIVB		
0	0	0	Way 0 line was invalid	No hit
0	0	1	Way 0 valid, not modified	Way 0 valid, not modified
0	1	0	Way 0 line was invalid	No hit
0	1	1	Way 0 valid and modified	Way 0 valid and modified
1	0	0	Way 1 line was invalid	No hit
1	0	1	Way 1 valid, not modified	Way 1 valid, not modified
1	1	0	Way 1 line was invalid	No hit
1	1	1	Way 1 valid and modified	Way 1 valid and modified

At completion of a line command other than a write, the CCVR (Cache R/W Value Register) contains information on the initial state of the line tag or data targeted by the command. For line commands, CLCR[TDSEL] selects between tag and data. If the line command used a physical address and missed, the data is don't care. For write commands, the CCVR holds the write data.

Chapter 30
Quad Serial Peripheral Interface (QuadSPI)

30.1 Introduction

The Quad Serial Peripheral Interface (QuadSPI) block acts as an interface to one single or two external serial flash devices, each with up to four bidirectional data lines.

30.1.1 Features

The QuadSPI supports the following features:

- Flexible sequence engine to support various flash vendor devices.
- Single, dual, quad and octal mode of operation.
- DDR/DTR mode wherein the data is generated on every edge of the serial flash clock.
- Support for flash data strobe signal for data sampling in DDR and SDR mode.
- Support for parallel writes via register mapped interface in single io mode.
- Two identical serial flash devices can be connected and accessed in parallel for data read operations, forming one (virtual) flash memory with doubled readout bandwidth.
- DMA support to read RX Buffer data via AMBA AHB bus (64-bit width interface) or IP registers space (32-bit access).
    - Inner loop size of DMA access can be configured.
- Multi master accesses with priority
    - Flexible and configurable buffer for each master
- Fourteen interrupt conditions (see Table 30-425)

- Memory mapped read access to connected flash devices.
- Programmable sequence engine to cater to future command/protocol changes and able to support all existing vendor commands and operations.
    - Supports 3-byte and 4-byte addressing.

30.1.2 Block Diagram

The following figure is a block diagram of the Quad Serial Peripheral Interface (QuadSPI) module.

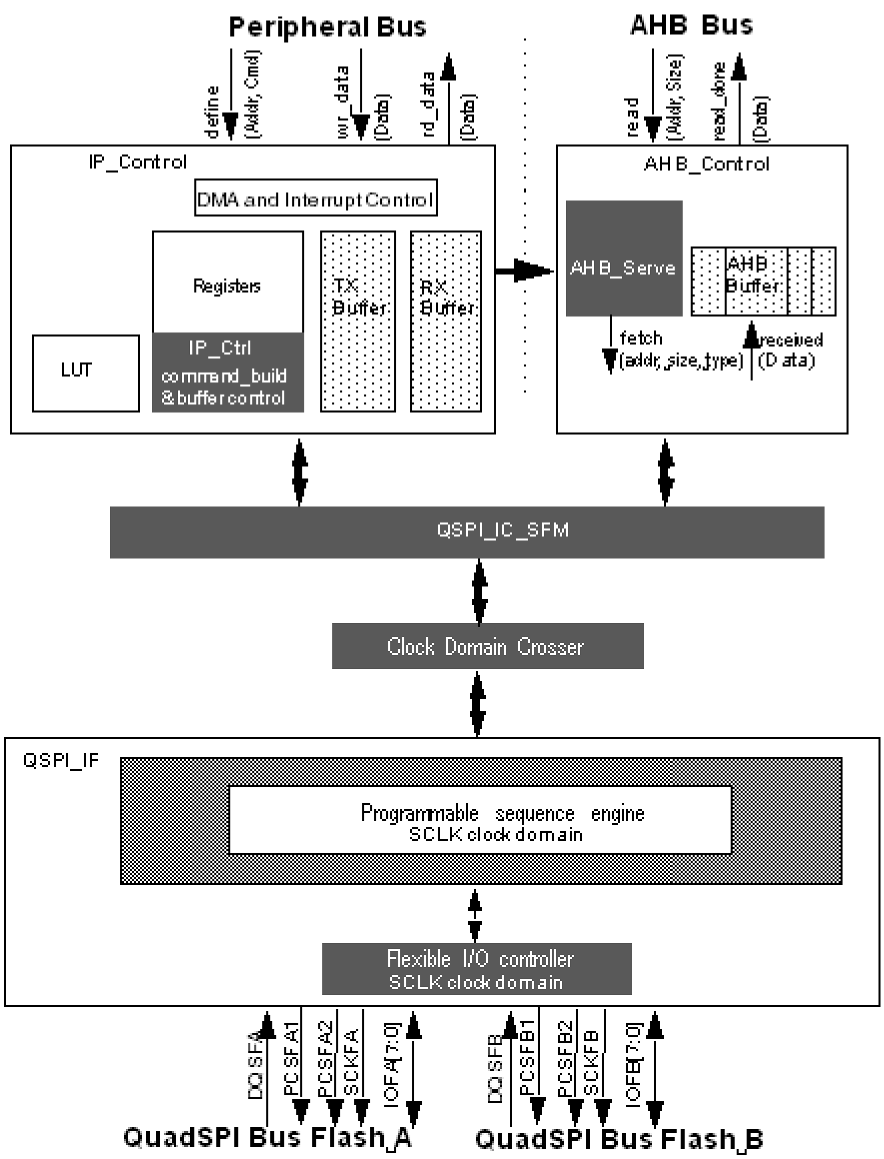

Figure 30-1. QuadSPI Block Diagram

30.1.3 QuadSPI Modes of Operation

This section provides information about the modes in which the QuadSPI module can be used.

30.1.3.1 Normal Mode

In this mode one or two external serial flash memory device can be accessed. Further details about this mode of operation can be found in Modes of Operation(Normal Mode) section.

30.1.3.2 Module Disable Mode

The Module Disable Mode is used for power management of the device containing the QuadSPI module, it is controlled by signals external to the QuadSPI. The clock to the non-memory mapped logic in the QuadSPI can be stopped while in the Module Disable Mode.

30.1.3.3 Stop Mode

The Stop Mode is also used for power management. When a request is made to enter Stop Mode, the QuadSPI block completes the action currently being processed, before the request is acknowledged.

30.1.4 Acronyms and Abbreviations

The following table contains acronyms and abbreviations used in this document.

Table 30-1. Acronyms and Abbreviations

Terms	Description
AHB	Advanced High-performance Bus, version of AMBA
AMBA	Advanced Microcontroller Bus Architecture
BE	Big Endian Byte Ordering
CS	Chip Select.
DMA	Direct Memory Access.
MB	Megabyte. Each MB is 1024 * 1024 bytes

Table continues on the next page...

Table 30-1. Acronyms and Abbreviations (continued)

Terms	Description
IFM	Individual Flash Mode
PFM	Parallel Flash Mode
LSB	Least Significant Bit
MSB	Most Significant Bit
PCS	Peripheral Chip Select
QSPI, QuadSPI	Quad Serial Peripheral Interface
SCK	Serial Communications Clock
w1c	Write 1 to clear, writing a '1' to this field resets the flag

30.1.5 Glossary for QuadSPI module

Table 30-2. Glossary

Term	Definition
AHB Command	An AHB Command is a SFM Command triggered by a read access to the address range belonging to the memory mapped access defined in Table 30-388. Refer to AHB Commands for details.
Asserted	A signal that is asserted is in its active state. An active low signal changes from logic level one to logic level zero when asserted, and an active high signal changes from logic level zero to logic level one.
Clear	To clear a bit or bits means to establish logic level zero on the bit or bits.
Clock Phase	Determines when the data should be sampled relative to the active edge of SCK
Clock Polarity	Determines the idle state of the SCK signal.
Drain	To remove entries from a FIFO by software or hardware.
Endianess	Byte Ordering scheme.
Field	Two or more register bits grouped together.
Fill	To add entries to a FIFO by software or hardware.
Host	Refers to another functional block in the device containing the QuadSPI module
Instruction Code	8 bits defining the type of command to be executed.
IP Command	An IP Command is a SFM Command triggered by writing into the QSPI_IPCR[SEQID] field.
Logic level one	The voltage that corresponds to Boolean true (1) state.
Logic level zero	The voltage that corresponds to Boolean false (0) state.
Negated	A signal that is negated is in its inactive state. An active low signal changes from logic level '0' to logic level '1' when negated, and an active high signal changes from logic level '1' to logic level '0'.
QSPI_AMBA_BASE	First address of QuadSPI address space on system memory map.
QSPI_ARDB_BASE	First address of QuadSPI Rx Buffer on system memory map.
Set	To set a bit or bits means to establish logic level one on the bit or bits.

Table continues on the next page...

Table 30-2. Glossary (continued)

Term	Definition
RX Buffer PUSH Event	Addition of valid entries into the RX Buffer. In the default case each Buffer PUSH Event adds 2 entries to the RX Buffer since the interface to the serial clock domain is 64 bits in width. Depending on the number of bytes read from the serial flash device it is possible for the very last Buffer PUSH Event that only one entry is added. The QSPI_RBSR[RDBFL] field is incremented by the number of entries added to the RX Buffer.
RX Buffer POP Event	Removal of valid entries from the RX Buffer. Each Buffer POP Event removes (QSPI_RBCT[WMRK] + 1) valid entries from the buffer. The QSPI_RBSR[RDBFL] field is decremented by the same number and the QSPI_RBSR[RDCTR] field is incremented accordingly.
Individual Flash Mode	Access to a single, individual serial flash device. Refer to Serial Flash Access Schemes for details.
Parallel Flash Mode	Read access to two serial flash devices attached to the QuadSPI module in parallel. Refer to Serial Flash Access Schemes for details.
SFM Command	Serial Flash Memory Command. A SFM command consists of an instruction code and all other parameters (e.g. size or mode bytes) needed for that specific instruction code. Triggering a command either initiates a transaction on the external serial flash or results in an error. Refer to Table 30-436 for details on errors.
Single/Dual/Quad Instructions	Depending from the serial flash device connected to the QuadSPI module there will be instructions using a different number of data lines. • Single: Single line I/O with one data out and one data in line to/from the serial flash device. • Dual: Dual line I/O with two bidirectional I/O lines, driven alternatively by the serial flash device or the QuadSPI module • Quad: Quad line I/O with 4 bidirectional I/O lines, driven alternatively by the serial flash device or the QuadSPI
Transaction	A transaction consists of all flags, data and signals in either direction to execute a command for an attached serial flash device. It is a combination of chip select, sclk, instruction code, address, mode- and/or dummy bytes, transmit and/or receive data.
LUT	Look-up-table.

30.2 External Signal Description

This section provides the external signal information of the QuadSPI module.

The following table lists the external signals belonging to the QuadSPI, module in conjunction with the different modes of operation.

Table 30-3. Signal Properties

Signal Name	Function	Direction	Description
PCSFA1	Peripheral Chip Select Flash A1	O	This signal is the chip select for the serial flash device A1. A1 represents the first device in a dual-die package flash A or the first of the two flash devices that share IOFA. Refer to Dual Die Flashes for more details.
PCSFA2	Peripheral Chip Select Flash A2	O	This signal is the chip select for the serial flash device A2. A2 represents the second device in a dual-die package flash A or the second of the two flash devices that share IOFA. Refer to Dual Die Flashes for more details.

Table continues on the next page...

Table 30-3. Signal Properties (continued)

Signal Name	Function	Direction	Description
PCSFB1	Peripheral Chip Select Flash B1	O	This signal is the chip select for the serial flash device B1. B1 represents the first device in a dual-die package flash B or the first of the two flash devices that share IOFB. Refer to Dual Die Flashes for more details.
PCSFB2	Peripheral Chip Select Flash B2	O	This signal is the chip select for the serial flash device B2. B2 represents the second device in a dual-die package flash B or the second of the two flash devices that share IOFB. Refer to Dual Die Flashes for more details.
SCKFA	Serial Clock Flash A	O	This signal is the serial clock output to the serial flash device A.
SCKFB	Serial Clock Flash B	O	This signal is the serial clock output to the serial flash device B.
IOFA[7:0]	Serial I/O Flash A	I/O	These signals are the data I/O lines to/from the serial flash device A. Refer to Driving External Signals for details about the signal drive and timing behavior. Note that the signal pins of the serial flash device may change their function according to the SFM Command executed, leaving them as control inputs when Single and Dual Instructions are executed. The QuadSPImodule supports driving these inputs to dedicated values. During the execution of Single and Dual Instructions, the logic level which is applied to the IOFA[3] and IOFA[2] output signals, is determined by the QSPI_MCR[ISD3FA] and the QSPI_MCR[ISD2FA] bits.
IOFB[7:0]	Serial I/O Flash B	I/O	These signals are the data I/O lines to/from the serial flash device B. Refer to Driving External Signals for details about the signal drive and timing behavior. Note that the signal pins of the serial flash device may change their function according to the SFM Command executed, leaving them as control inputs when Single and Dual Instructions are executed. The QuadSPImodule supports driving these inputs to dedicated values. During the execution of Single and Dual Instructions the logic level which is applied to the IOFB[3] and IOFB[2] output signals is determined by the QSPI_MCR[ISD3FB] and the QSPI_MCR[ISD2FB] bits.
DQSFA	Data Strobe signal Flash A	I	Data strobe signal for port A. Some flash vendors provide the DQS signal to which the read data is aligned in DDR mode.
DQSFB	Data Strobe signal Flash B	I	Data strobe signal for port B. Some flash vendors provide the DQS signal to which the read data is aligned in DDR mode.

30.2.1 Driving External Signals

The different phases of serial flash access scheme are shown in the following figure.

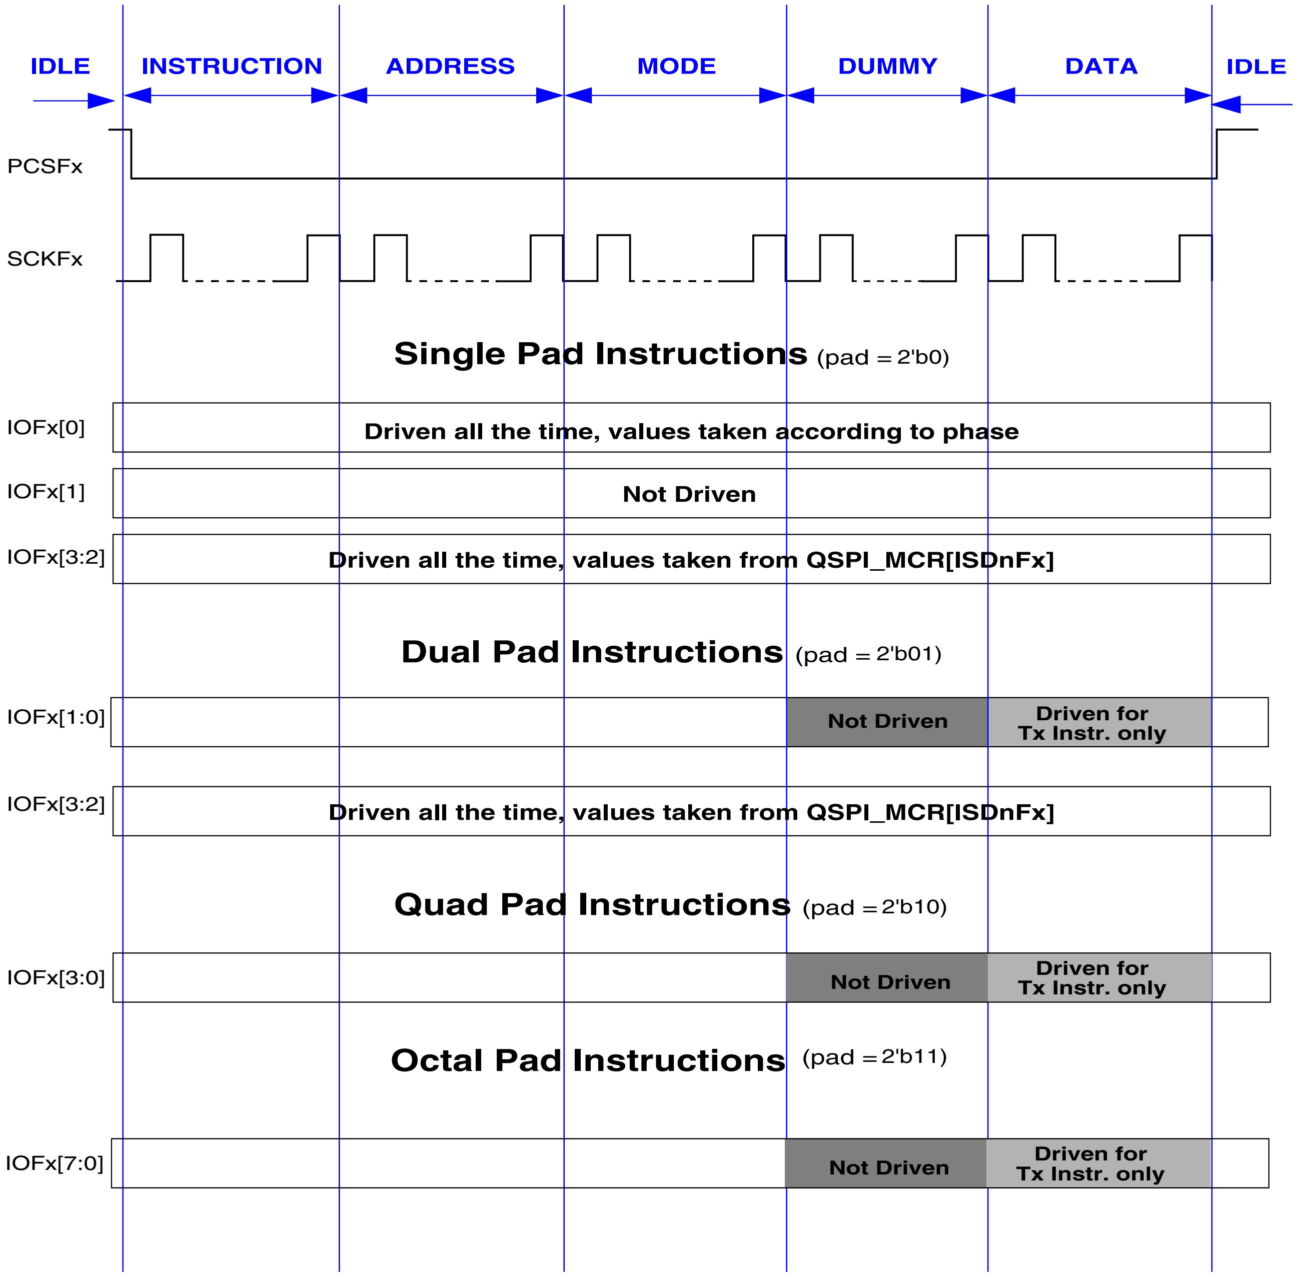

Figure 30-2. Serial Flash Access Scheme

The different phases and the I/O driving characteristics of the QuadSPI module are characterized in the following way:

- IDLE: Serial flash device not selected. No interaction with the serial flash device. All IOFx signals driven.
- INSTRUCTION: Serial flash device selected. The instruction is sent to the serial flash device. All IOFx signals are driven.

- ADDRESS: Serial Flash Address is sent to the device. All IOFx signals are driven. Note that this phase is not applicable for all SFM Commands.
- MODE: Mode bytes are sent to the serial flash device. All IOFx signals are driven. Note that this phase is not applicable for all SFM Commands.
- DUMMY: Dummy clocks are provided to the serial flash device. Refer to the Figure 30-2 for the IOFx signals driven. The actual data lines required for the SFM Command executed are not driven for data read commands. Note that this phase is not applicable for all SFM Commands.
- DATA: Serial flash data are sent to or received from the serial flash device. Refer to the preceding figure for the IOFx signals driven. The actual data lines required for the SFM Command executed are not driven for data read commands. Note that this phase is not applicable for all SFM Commands.

The PCSFx and SCKFx signals are driven permanently throughout all the phases.

In Individual Flash Mode this applies to the selected flash device. In Parallel Flash Mode this applies to both serial flash devices simultaneously.

30.3 Memory Map and Register Definition

This section provides the memory map and register definitions of the QuadSPI module.

30.3.1 Register Write Access

This section describes the write access restriction terms that apply to all registers, which can be one of the following:

- **Register Write Access Restriction**

  For each register bit and register field, the write access conditions are specified in the detailed register description. A description of the write access conditions is given in the following table. If, for a specific register bit or field, none of the given write access conditions is fulfilled, any write attempt to this register bit or field is ignored without any notification. The values of the bits or fields are not changed.

  The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled.

Table 30-4. Register Write Access Restrictions

Condition	Description
Anytime	No write access restriction.
Disabled Mode	Write access only if *QSPI_MCR[MDIS] = 1*.
Normal Mode	Write access only if the module is in *Normal Mode*.

- **Register Write Access Requirements**

  All registers can be accessed with 8-bit, 16-bit, and 32-bit wide operations. For some of the registers, at least a 16/32-bit wide write access is required to ensure correct operation. This write access requirement is stated in the detailed register description for each register affected.

30.3.2 Peripheral Bus Register Descriptions

This section provides the peripheral bus register information of the QuadSPI module. For register diagram and description table, please refer to Section "Peripheral Bus Memory Map and Registers".

This section provides the memory map and register definitions of the QuadSPI module.

QuadSPI memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

30.32.1 Module Configuration Register (QuadSPIx_MCR)

The QuadSPI_MCR holds configuration data associated with QuadSPI operation.

Write:

- *All other fields: Anytime*

Address: Base address + 0h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R/W	Reserved								Reserved				Reserved			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	Reserved	MDIS	Reserved		CLR_TXF	CLR_RXF	Reserved		DDR_EN	DQS_EN	Reserved		END_CFG		SWRSTHD	SWRSTSD
Reset	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_MCR field descriptions

Field	Description
31–24 Reserved	This field is reserved. This field is reserved and should always be set to 0.
23–20 Reserved	This field is reserved.
19–16 Reserved	This field is reserved. This field is reserved and should always be set to 0xF.
15 Reserved	This field is reserved. This field is reserved.
14 MDIS	Module Disable. The MDIS bit allows the clock to the non-memory mapped logic in the QuadSPI to be stopped, putting the QuadSPI in a software controlled power-saving state. Please refer to , for more information. 0 Enable QuadSPI clocks. 1 Allow external logic to disable QuadSPI clocks.
13–12 Reserved	This field is reserved.
11 CLR_TXF	Clear TX FIFO/Buffer. Invalidate the TX Buffer content. 0 No action. 1 Read and write pointers of the TX Buffer are reset to 0. QSPI_TBSR[TRCTR] is reset to 0.
10 CLR_RXF	Clear RX FIFO. Invalidate the RX Buffer.

Table continues on the next page...

QuadSPIx_MCR field descriptions (continued)

Field	Description
	0 No action. 1 Read and write pointers of the RX Buffer are reset to 0. QSPI_RBSR[RDBFL] is reset to 0.
9–8 Reserved	This field is reserved.
7 DDR_EN	DDR mode enable: 0 2x and 4x clocks are disabled for SDR instructions only 1 2x and 4x clocks are enabled supports both SDR and DDR instruction.
6 DQS_EN	DQS enable: This field is valid only when the DDR_EN field is set.For more details Refer Data Strobe Signal Functionality 0 DQS disabled. 1 DQS enabled- When enabled, the incoming data is sampled on both the edges of DQS input. The QSPI_SMPR[DDR_SMP] values are ignored.
5–4 Reserved	This field is reserved.
3–2 END_CFG	Defines the endianness of the QSPI module.For more details refer to Byte Ordering Endianess
1 SWRSTHD	Software reset for AHB domain 0 No action 1 AHB domain flops are reset. Does not reset configuration registers. It is advisable to reset both the serial flash domain and AHB domain at the same time. Resetting only one domain might lead to side effects.
0 SWRSTSD	Software reset for Serial Flash domain 0 No action 1 Serial Flash domain flops are reset. Does not reset configuration registers. It is advisable to reset both the serial flash domain and AHB domain at the same time. Resetting only one domain might lead to side effects.

30.32.2 IP Configuration Register (QuadSPIx_IPCR)

The IP configuration register provides all the configuration required for an IP initiated command. An IP command can be triggered by writing in the SEQID field of this register. If the SEQID field is written successfully, a new command to the external serial flash is started as per the sequence pointed to by the SEQID field. Refer to Normal Mode , for details about the command triggering and command execution.

Write:

- *QSPI_SR[IP_ACC]=0*

Address: Base address + 8h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R/W	Reserved				SEQID				Reserved							PAR_EN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	IDATSZ															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_IPCR field descriptions

Field	Description
31–28 Reserved	This field is reserved.
27–24 SEQID	Points to a sequence in the Look-up-table. The SEQID defines the bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. Refer to Look-up Table for more details. A write to this bit -field triggers a transaction on the serial flash interface.
23–17 Reserved	This field is reserved.
16 PAR_EN	When set, a transaction to two serial flash devices is triggered in parallel mode. Refer to Parallel Flash Mode for more details.
15–0 IDATSZ	IP data transfer size: Defines the data transfer size in bytes of the IP command.

30.32.3 Flash Configuration Register (QuadSPIx_FLSHCR)

The Flash configuration register contains the flash device specific timings that must be met by the QuadSPI controller for the device to function correctly.

Write:

- *QSPI_SR[AHB_ACC] = 0*
- *QSPI_SR[IP_ACC] = 0*

Address: Base address + Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	Reserved																				TCSH				Reserved				TCSS			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	1	1

QuadSPIx_FLSHCR field descriptions

Field	Description
31–12 Reserved	This field is reserved. Reserved.
11–8 TCSH	Serial flash CS hold time in terms of serial flash clock cycles.
7–4 Reserved	This field is reserved. Reserved.
3–0 TCSS	Serial flash CS setup time in terms of serial flash clock cycles.

30.32.4 Buffer0 Configuration Register (QuadSPIx_BUF0CR)

This register provides the configuration for any access to buffer0. An access is routed to buffer0 when the master port number of the incoming AHB request matches the MSTRID field of the BUF0CR. Any buffer "miss" leads to a serial flash transaction being triggered as per the sequence pointed to the SEQID field. Buffer0 may also be configured as a high priority buffer by setting the HP_EN field of this register.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: Base address + 10h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	HP_EN	Reserved														
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADATSZ								Reserved				MSTRID			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_BUF0CR field descriptions

Field	Description
31 HP_EN	High Priority Enable: When set, the master associated with this buffer is assigned a priority higher than the rest of the masters. An access by a high priority master will suspend any ongoing prefetch by another AHB master and will be serviced on high priority. Refer to Flexible AHB Buffers for details.
30–16 Reserved	This field is reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash. For example,a value of 0x2 will set transfer size to 16bytes.When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved. Reserved.

Table continues on the next page...

QuadSPIx_BUF0CR field descriptions (continued)

Field	Description
3–0 MSTRID	Master ID: The ID of the AHB master associated with BUFFER0. Any AHB access with this master port number is routed to this buffer.

30.32.5 Buffer1 Configuration Register (QuadSPIx_BUF1CR)

This register provides the configuration for any access to buffer1. An access is routed to buffer1 when the master port number of the incoming AHB request matches the MSTRID field of the BUF1CR. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: Base address + 14h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved																ADATSZ								Reserved				MSTRID			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_BUF1CR field descriptions

Field	Description
31–16 Reserved	This field is reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 bytes of an AHB triggered access to serial flash.For example, a value of 0x2 will set transfer size to 16bytes. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved.
3–0 MSTRID	Master ID: The ID of the AHB master associated with BUFFER1. Any AHB access with this master port number is routed to this buffer.

30.32.6 Buffer2 Configuration Register (QuadSPIx_BUF2CR)

This register provides the configuration for any access to buffer2. An access is routed to buffer2 when the master port number of the incoming AHB request matches the MSTRID field of the BUF2CR. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: Base address + 18h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_BUF2CR field descriptions

Field	Description
31–16 Reserved	This field is reserved. Reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 Bytes of an AHB triggered access to serial flash. For example, a value of 0x2 will set transfer size to 16bytes.When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved. Reserved.
3–0 MSTRID	Master ID: The ID of the AHB master associated with BUFFER2. Any AHB access with this master port number is routed to this buffer.

30.32.7 Buffer3 Configuration Register (QuadSPIx_BUF3CR)

This register provides the configuration for any access to buffer3. An access is routed to buffer3 when the master port number of the incoming AHB request matches the MSTRID field of the BUF3CR. Any buffer "miss" leads to the buffer being flushed a serial flash transaction being triggered as per the sequence pointed to by the SEQID field. If the ALLMST field is set, any transaction where the master port number does not match any of the buffer MSTRID fields will be routed to this buffer. In the case that the ALLMST field is not set, any such transaction (where master port number does not match any of the MSTRID fields) will be returned an ERROR response.

Write:

- *QSPI_SR[AHB_ACC] = 0*

.

Address: Base address + 1Ch offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

QuadSPIx_BUF3CR field descriptions

Field	Description
31 ALLMST	All master enable: When set, buffer3 acts as an all-master buffer. Any AHB access with a master port number not matching with the master ID of buffer0 or buffer1 or buffer2 is routed to buffer3. When set, the MSTRID field of this register is ignored.
30–16 Reserved	This field is reserved. Reserved.
15–8 ADATSZ	AHB data transfer size: Defines the data transfer size in 8 Bytes of an AHB triggered access to serial flash. When ADATSZ = 0, the data size mentioned the sequence pointed to by the SEQID field overrides this value. SW should ensure that this transfer size is not greater than the size of this buffer.
7–4 Reserved	This field is reserved.
3–0 MSTRID	Master ID: The ID of the AHB master associated with BUFFER3. Any AHB access with this master port number is routed to this buffer.

30.32.8 Buffer Generic Configuration Register (QuadSPIx_BFGENCR)

This register provides the generic configuration to any of the buffer accesses. Any buffer "miss" leads to the buffer being flushed and a serial flash transaction being triggered as per the sequence pointed to by the SEQID field. If the PAR_EN field is set, all the buffer accesses result in parallel accesses to the flashes.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: Base address + 20h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

QuadSPIx_BFGENCR field descriptions

Field	Description
31–17 Reserved	This field is reserved.
16 PAR_EN	When set, a transaction to two serial flash devices is triggered in parallel mode. Refer to Parallel Flash Mode for more details.
15–12 SEQID	Points to a sequence in the Look-up-table. The SEQID defines the bits [6:2] of the LUT index. The bits [1:0] are always assumed to be 0. Refer to Look-up Table. **NOTE:** If the sequence pointer differs between the new and previous sequence then the user should reset this. See QSPI_SPTRCLR for more information.
11–0 Reserved	This field is reserved.

30.32.9 Buffer0 Top Index Register (QuadSPIx_BUF0IND)

This register specifies the top index of buffer0, which defines its size. Note that that the 3 LSBs of this register are set to zero - this ensures that the buffer is 64bit aligned, as each buffer entry is 64bits long.

The register value should be set to the desired number of bytes less 8. For example, setting BUF0IND to 0 gives 8 bytes, 1 give 16bytes etc.

The size of buffer0 is the difference between the BUF0IND+8 and 0.

It is the responsibility of the software to ensure that BUF0IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: Base address + 30h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_BUF0IND field descriptions

Field	Description
31–3 TPINDX0	Top index of buffer 0.
2–0 Reserved	This field is reserved. Reserved.

30.32.10 Buffer1 Top Index Register (QuadSPIx_BUF1IND)

This register specifies the top index of buffer1, which defines its size. Note that the 3 LSBs of this register are set to zero - this ensures that the buffer is 64bit aligned as each buffer entry is 64bits long.

The register value should be set to the desired number of bytes less. The size of buffer1 is the difference between the BUF1IND and BUF0IND.

It is the responsibility of the software to ensure that BUF1IND value is not greater than the overall size of the buffer. The hardware does not provide any protection against illegal programming.

Write:

- *QSPI_SR[AHB_ACC] = 0*

Address: Base address + 34h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Field	Description
31–3 TPINDX2	Top index of buffer 2.
2–0 Reserved	This field is reserved.

30.32.12 Serial Flash Address Register (QuadSPIx_SFAR)

The module automatically translates this address on the memory map to the address on the flash itself. When operating in 24bit mode, only bits 23-0 are sent to the flash, in 32bit mode, bits 27-0 are used with bits 31-28 driven to 0. Refer to Table 30-386 for the mapping between the access mode and the QSPI_SFAR content and to Normal Mode for details about the command triggering and command execution. The software should ensure that the serial flash address provided in the QSPI_SFAR register lies in the valid flash address range as defined in Table 30-386.

Write:

- *QSPI_SR[IP_ACC] = 0*

Address: Base address + 100h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_RBSR field descriptions

Field	Description
31–16 RDCTR	Read Counter, indicates how many entries of 4 bytes have been removed from the RX Buffer.For example a value of 0x2 would indicate 8bytes have been removed It is incremented by the number (QSPI_RBCT[WMRK] + 1) on RX Buffer POP event. The RX Buffer can be popped using DMA or pop flag QSPI_FR[RBDF]. The QSPI_RSER[RBDDE] defines which pop has to be done. For further details please refer to AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31) and "Data Transfer from the QuadSPI Module Internal Buffers section in Flash Read section.
15–14 Reserved	This field is reserved.
13–8 RDBFL	RX Buffer Fill Level, indicates how many entries of 4 bytes are still available in the RX Buffer.For example a value of 0x2 would indicate 8bytes are available.
7–0 Reserved	This field is reserved.

30.32.15 RX Buffer Control Register (QuadSPIx_RBCT)

This register contains control data related to the receive data buffer.

Write:

- *QSPI_SR[IP_ACC] = 0*

Address: Base address + 110h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_RBCT field descriptions

Field	Description
31–9 Reserved	This field is reserved.
8 RXBRD	RX Buffer Readout: This bit specifies the access scheme for the RX Buffer readout.

Table continues on the next page...

QuadSPIx_RBCT field descriptions (continued)

Field	Description
	0 RX Buffer content is read using the AHB Bus registers QSPI_ARDB0 to QSPI_ARDB31. For details, refer to Exclusive Access to Serial Flash for AHB Commands. 1 RX Buffer content is read using the IP Bus registers QSPI_RBDR0 to QSPI_RBDR31.
7–5 Reserved	This field is reserved.
4–0 WMRK	RX Buffer Watermark: This field determines when the readout action of the RX Buffer is triggered. When the number of valid entries in the RX Buffer is equal to or greater than the number given by (WMRK+1) the QSPI_SR[RXWE] flag is asserted.The value should be entered as the number of 4byte entries minus 1. For example a value of 0x0 would set the watermark to 4bytes, 1 to 8bytes, 2 to 12bytes etc. For details, refer to DMA Usage.

30.32.16 TX Buffer Status Register (QuadSPIx_TBSR)

This register contains information related to the transmit data buffer.

Address: Base address + 150h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

QuadSPIx_TBSR field descriptions

Field	Description
31–16 TRCTR	Transmit Counter. This field indicates how many entries of 4 bytes have been written into the TX Buffer by host accesses. It is reset to 0 when a 1 is written into the QSPI_MCR[CLR_TXF] bit. It is incremented on each write access to the QSPI_TBDR register when another word has been pushed onto the TX Buffer. When it is not cleared the TRCTR field wraps around to 0. Refer to TX Buffer Data Register (QuadSPI_TBDR) for details.
15–13 Reserved	This field is reserved.
12–8 TRBFL	TX Buffer Fill Level. The TRBFL field contains the number of entries of 4 bytes each available in the TX Buffer for the QuadSPI module to transmit to the serial flash device.
7–0 Reserved	This field is reserved.

30.32.17 TX Buffer Data Register (QuadSPIx_TBDR)

The QSPI_TBDR register provides access to the circular TX Buffer of depth 64 bytes. This buffer provides the data written into it as write data for the page programming commands to the serial flash device. Refer to Table 30-429 for the byte ordering scheme. A write transaction on the flash with data size of less than 32 bits will lead to the removal of one data entry from the TX buffer. The valid bits will be used and the rest of the bits will be discarded.

Write:

- *QSPI_SR[TXFULL] = 0*

32-bit write access required

Address: Base address + 154h offset

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_SR field descriptions

Field	Description
31–29 DLPSMP	Data learning pattern sampling point: The sampling point found by the controller with the data learning pattern. • This is used for DDR only. • If the learning fails, this field will return garbage and DLPFF bit will be set.
28 Reserved	This field is reserved.
27 TXFULL	TX Buffer Full: Asserted when no more data can be stored.
26–25 Reserved	This field is reserved.
24 TXNE	TX Buffer Not Empty: Asserted when TX Buffer contains data.
23 RXDMA	RX Buffer DMA: Asserted when RX Buffer read out via DMA is active i.e DMA is requested or running.
22–20 Reserved	This field is reserved.

Table continues on the next page...

QuadSPIx_SR field descriptions (continued)

Field	Description
19 RXFULL	RX Buffer Full: Asserted when the RX Buffer is full, i.e. that QSPI_RBSR[RDBFL] field is equal to 32.
18–17 Reserved	This field is reserved.
16 RXWE	RX Buffer Watermark Exceeded: Asserted when the number of valid entries in the RX Buffer exceeds the number given in the QSPI_RBCT[WMRK] field.
15 Reserved	This field is reserved.
14 AHB3FUL	AHB 3 Buffer Full: Asserted when AHB 3 buffer is full.
13 AHB2FUL	AHB 2 Buffer Full: Asserted when AHB 2 buffer is full.
12 AHB1FUL	AHB 1 Buffer Full: Asserted when AHB 1 buffer is full.
11 AHB0FUL	AHB 0 Buffer Full: Asserted when AHB 0 buffer is full.
10 AHB3NE	AHB 3 Buffer Not Empty: Asserted when AHB 3 buffer contains data.
9 AHB2NE	AHB 2 Buffer Not Empty: Asserted when AHB 2 buffer contains data.
8 AHB1NE	AHB 1 Buffer Not Empty: Asserted when AHB 1 buffer contains data.
7 AHB0NE	AHB 0 Buffer Not Empty: Asserted when AHB 0 buffer contains data.
6 AHBTRN	AHB Access Transaction pending: Asserted when there is a pending request on the AHB interface. Refer to the AMBA specification for details.
5 AHBGNT	AHB Command priority Granted: Asserted when another module has been granted priority of AHB Commands against IP Commands. For details refer to Command Arbitration.
4 Reserved	This field is reserved.
3 RESERVED	This field is reserved.
2 AHB_ACC	AHB Access: Asserted when the transaction currently executed was initiated by AHB bus.
1 IP_ACC	IP Access: Asserted when transaction currently executed was initiated by IP bus.
0 BUSY	Module Busy: Asserted when module is currently busy handling a transaction to an external flash device.

30.32.19 Flag Register (QuadSPIx_FR)

The QSPI_FR register provides all available flags about SFM command execution and arbitration which may serve as source for the generation of interrupt service requests. Note that the error flags in this register do not relate directly to the execution of the transaction in the serial flash device itself but only to the behavior and conditions visible in the QuadSPI module.

Write:Enabled Mode

Address: Base address + 160h offset

QuadSPIx_FR field descriptions

Field	Description
31 DLPFF	Data Learning Pattern Failure Flag: Set when DATA_LEARN instruction was encountered in a sequence but no sampling point was found for the data learning pattern. The controller automatically starts sampling using the value in QSPI_SMPR[DDRSMP].
30–29 RESERVED	This field is reserved.
28 Reserved	This field is reserved.
27 TBFF	TX Buffer Fill Flag: Before writing to the TX buffer, this bit should be cleared. Then this bit has to be read back. If the bit is set, the TX Buffer can take more data. If the bit remains cleared, the TX buffer is full. Refer to Tx Buffer Operation for details.
26 TBUF	TX Buffer Underrun Flag: Set when the module tried to pull data although TX Buffer was empty. The IP Command leading to the TX Buffer underrun is continued (data sent to the serial flash device is undefined). The application must clear the TX Buffer in response to this event by writing a 1 into the QSPI_MCR[CLR_TXF] bit.
25–24 Reserved	This field is reserved.
23 ILLINE	Illegal Instruction Error Flag: Set when an illegal instruction is encountered by the controller in any of the sequences. Refer to Table 30-427 for a list of legal instructions.
22–18 Reserved	This field is reserved.
17 RBOF	RX Buffer Overflow Flag: Set when not all the data read from the serial flash device could be pushed into the RX Buffer. The IP Command leading to this condition is continued until the number of bytes according to the QSPI_IPCR[IDATSZ] field has been read from the serial flash device. The content of the RX Buffer is not changed.

Table continues on the next page...

QuadSPIx_FR field descriptions (continued)

Field	Description
16 RBDF	RX Buffer Drain Flag: Will be set if the QuadSPI_SR[RXWE] status bit is asserted. Writing 1 into this bit triggers one of the following actions: • If the RX Buffer has up to QuadSPI_RBCT[WMRK] valid entries then the flag is cleared. • If the RX Buffer has more than QuadSPI_RBCT[WMRK] valid entries and the QuadSPI_RSER[RBDDE] bit is not set (flag driven mode) a RX Buffer POP event is triggered. The flag remains set if the RX Buffer contains more than QuadSPI_RBCT[WMRK] valid entries after the RX Buffer POP event is finished. The flag is cleared if the RX Buffer contains less than or equal to QuadSPI_RBCT[WMRK] valid entries after the RX Buffer POP event is finished. Refer to "Receive Buffer Drain Interrupt or DMA Request" section in Normal Mode Interrupt and DMA Requests, for details.
15 ABSEF	AHB Sequence Error Flag: Set when the execution of an AHB Command is started with an WRITE or WRITE_DDR Command in the sequence pointed to by the QSPI_BUFxCR [1] register No communication with the serial flash device is initiated by the QuadSPI module. The AHB bus request which triggered this command is answered with an ERROR response.
14 AITEF	AHB Illegal transaction error flag.Set whenever there is no response generated from QSPI to AHB bus in case of illegal transaction and the watchdog timer expires.The timer value is taken as parameter.
13 AIBSEF	AHB Illegal Burst Size Error Flag: Set whenever the total burst size(size x beat) of an AHB transaction is greater than the prefetch data size. The prefecth data size is defined by QSPI_BUFxCR[ADATSZ] or data size mentioned in the sequence pointed to by the SEQID field in case ADATSZ =0. Refer to HBURST Support for more details on hburst feature.
12 ABOF	AHB Buffer Overflow Flag: Set when the size of the AHB access exceeds the size of the AHB buffer. This condition can occur only if the QSPI_BUFxCR[ADATSZ] field is programmed incorrectly. The AHB Command leading to this condition is continued until the number of entries according to the QSPI_BUFxCR[ADATSZ] field has been read from the serial flash device. The content of the AHB Buffer is not changed.
11 IUEF	IP Command Usage Error Flag: Set when in parallel flash mode the execution of an IP Command is started with more than one pad enabled and the sequence pointed to by the sequence ID contains a WRITE or a WRITE_DDR command. Refer to Table 30-427 table for the related commands. No communication with the serial flash device is initiated by the QuadSPI module.
10–8 Reserved	This field is reserved.
7 IPAEF	IP Command Trigger during AHB Access Error Flag. Set when the following condition occurs: • A write access occurs to the QSPI_IPCR[SEQID] field and the QSPI_SR[AHB_ACC] bit is set. Any command leading to the assertion of the IPAEF flag is ignored.
6 IPIEF	IP Command Trigger could not be executed Error Flag. Set when the QSPI_SR[IP_ACC] bit is set (i.e. an IP triggered command is currently executing) and any of the following conditions occurs: • Write access to the QSPI_IPCR register. Any command leading to the assertion of the IPIEF flag is ignored • Write access to the QSPI_SFAR register. • Write access to the QSPI_RBCT register.
5 Reserved	This field is reserved.
4 IPGEF	IP Command Trigger during AHB Grant Error Flag: Set when the following condition occurs: • A write access occurs to the QSPI_IPCR[SEQID] field and the QSPI_SR[AHBGNT] bit is set. Any command leading to the assertion of the IPGEF flag is ignored.

Table continues on the next page...

QuadSPIx_FR field descriptions (continued)

Field	Description
3–1 Reserved	This field is reserved.
0 TFF	IP Command Transaction Finished Flag: Set when the QuadSPI module has finished a running IP Command. If an error occurred the related error flags are valid, at the latest, in the same clock cycle when the TFF flag is asserted.

1. QSPI_BUFxCR implies anyone of QSPI_BUF0CR/QSPI_BUF1CR/QSPI_BUF2CR/QSPI_BUF3CR

30.32.20 Interrupt and DMA Request Select and Enable Register (QuadSPIx_RSER)

The QuadSPI_RSER register provides enables and selectors for the interrupts in the QuadSPI module.

NOTE

Each flag of the QuadSPI_FR register enabled as source for an interrupt prevents the QuadSPI module from entering Stop Mode or Module Disable Mode when this flag is set.

>

7–6 SPDBUF	Suspended Buffer: Provides the suspended buffer number. Valid only when SUSPND is set to 1'b1
5–1 Reserved	This field is reserved.
0 SUSPND	When set, it signifies that a sequence is in suspended state

30.32.22 Sequence Pointer Clear Register (QuadSPIx_SPTRCLR)

The sequence pointer clear register provides bits to reset the IP and Buffer sequence pointers. The sequence pointer contains the index of which instruction within the LUT entry is to be executed next. For example, if the LUT entry ends on a JMP_ON_CS value of 2, the index will be stored as 2.

The software should reset the sequence pointers whenever the sequence ID is changed by updating the SEQID field in QSPI_IPCR or QSPI_BFGENCR.

Address: Base address + 16Ch offset

30.32.27 RX Buffer Data Register (QuadSPIx_RBDR*n*)

The QuadSPI_RBDR registers provide access to the individual entries in the RX Buffer. Refer to Table 30-429 for the byte ordering scheme.

QuadSPI_RBDR0 corresponds to the actual position of the read pointer within the RX Buffer. The number of valid entries available depends from the number of RX Buffer entries implemented and from the number of valid buffer entries available in the RX Buffer.

Example 1, RX Buffer filled completely with 32 words: In this case the address range for valid read access extends from QuadSPI_RBDR0 to QuadSPI_RBDR31.

Example 2, RX Buffer filled with 5 valid words: RX Buffer fill level QuadSPI_RBSR[RDBFL] is 5. In this case an access to QuadSPI_RBDR4 provides the last valid entry.

Any access beyond the range of valid RX Buffer entries provides undefined results.

Address: Base address + 200h offset + (4d × i), where i=0d to 31d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

QuadSPIx_LCKCR field descriptions

Field	Description
31–2 Reserved	This field is reserved.
1 UNLOCK	Unlocks the LUT when the following two conditions are met: 1. This register is written just after the LUT Key Register (QuadSPI_LUTKEY) 2. The LUT key register was written with 0x5AF05AF0 key
0 LOCK	Locks the LUT when the following condition is met: 1. This register is written just after the LUT Key Register (QuadSPI_LUTKEY) 2. The LUT key register was written with 0x5AF05AF0 key

30.32.30 Look-up Table register (QuadSPIx_LUT0)

The LUT registers are a look-up-table for sequences of instructions. The programmable sequence engine executes the instructions in these sequences to generate a valid serial flash transaction. There are a total of 64 LUT registers. These 64 registers are divided into groups of 4 registers that make a valid sequence. Therefore, QSPI_LUT[0], QSPI_LUT[4], QSPI_LUT[8] ..... QSPI_LUT[60] are the starting registers of a valid sequence. Each of these sets of 4 registers can have a maximum of 8 instructions. A maximum of 16 sequences can be defined at one time. Look-up Table describes the LUT registers in detail.

Write:Once the LUT is unlocked

Address: Base address + 310h offset

7–0 OPRND0	Operand for INSTR0.

30.3.3 Serial Flash Address Assignment

The serial flash address assignment may be modified by writing into Serial Flash A1 Top Address (QuadSPI_SFA1AD) and Serial Flash A2 Top Address (QuadSPI_SFA2AD) for device A and into Serial Flash B1Top Address (QuadSPI_SFB1AD) and Serial Flash B2Top Address (QuadSPI_SFB2AD) for device B. The following table shows how different access modes are related to the address specified for the next SFM Command. Note that this address assignment is valid for both IP and AHB commands.

Table 30-386. Serial Flash Address Assignment

Parameter	Function	Access Mode
QSPI_AMBA_BASE ((31:10) - 22 bits)	QuadSPI AHB base address	
TOP_ADDR_MEMA1(TPADA1)	Top address for the external flash A1 (first device of the dual die flash A, or the first of the two independent flashes sharing the IOFA)	Any access to the address space between TOP_ADDR_MEMA1 and QSPI_AMBA_BASE will be routed to **Serial Flash A1**
TOP_ADDR_MEMA2(TPADA2)	Top address for the external flash A2 (second device of the dual die flash A, or the second of the two independent flashes sharing the IOFA).	Any access to the address space between TOP_ADDR_MEMA2 and TOP_ADDR_MEMA1 will be routed to **Serial Flash A2**
TOP_ADDR_MEMB1(TPADB1)	Top address for the external flash B1 (first device of the dual die flash B, or the first of the two independent flashes sharing the IOFB)	Any access to the address space between TOP_ADDR_MEMB1 and TOP_ADDR_MEMA2 will be routed to **Serial Flash B1**
TOP_ADDR_MEMB2(TPADB2)	Top address for the external flash B2 (second device of the dual die flash B or the second of the two independent flashes sharing the IOFB)	Any access to the address space between TOP_ADDR_MEMB2 and TOP_ADDR_MEMB1 will be routed to **Serial Flash A2**

30.3.4 AMBA Bus Register Memory Map

QSPI_AMBA_BASE defines the address to be used as start address of the serial flash device as defined by the system memory map..

Table 30-387. QuadSPI AMBA Bus Memory Map

Address	Register Name
Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A	

Table continues on the next page...

Table 30-387. QuadSPI AMBA Bus Memory Map (continued)

Address	Register Name
QSPI_AMBA_BASE to (TOP_ADDR_MEMA2 - 0x01)	Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A Refer to Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A for details and to Table 30-429 and Table 30-434 for information about the byte ordering.
Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B	
TOP_ADDR_MEMA2 to (TOP_ADDR_MEMB2 - 0x01)	Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B Refer to Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B for details and to Table 30-429 and Table 30-434 for information about the byte ordering.
Parallel Flash Mode	
QSPI_AMBA_BASE to (TOP_ADDR_MEMB2 - 0x01)	Parallel Flash Mode Refer to Parallel Flash Mode for details and to Table 30-433 and Table 30-434 for information about the byte ordering.
AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)	
QSPI_ARDB_BASE to… (32 * 4 Byte) QSPI_ARDB_BASE + 0x0000_01FF	AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31) Refer to Table 30-429 and Table 30-431 for information about the byte ordering.

Note

Any read access to non-implemented addresses will provide undefined results.

In case single die flash devices, TOP_ADDR_MEMA2 and TOP_ADDR_MEMB2 should be initialized/programmed to TOP_ADDR_MEMA1 and TOP_ADDR_MEMB1 respectively- in effect, setting the size of these devices to 0. This would ensure that the complete memory map is assigned to only one flash device.

Parallel Flash Mode is valid only for commands related to data read and data write in single io mode from the serial flash. The first device of flash A has to be paired with the first device of flash B and the second device of flash A has to be paired with the second device of flash B in parallel mode. Parallel mode is selected via the QSPI_BFGENCR[PAR_EN] bit for all masters in AHB driven mode and via the QSPI_IPCR[PAR_EN] in IP driven mode. In parallel mode, the incoming address (SFAR address in case of IP initiated transactions and the incoming AHB address in case of AHB initiated transactions) is divided by 2 and sent to the two flashes connected in parallel.

Any IP Command other than data read and write (through one pad) in Parallel Flash Mode will result in the assertion of the QSPI_FR[IUEF] flag and any AHB Command other than data read in Parallel Flash Mode will result in the assertion of the QSPI_FR[ABSEF] flag.

In the Individual Flash Modes, the 3/4 address bytes (as programmed in the instruction/operand in the sequence) available for the flash address is determined by SFADR [23:0] or SFADR [31:0]as given in the table above.

In Parallel Flash Mode, both flashes are read with the same starting address of 3/4 (as programmed in the instruction/operand in the sequence) bytes in size. This address is derived from SFADR [24:1] or SFADR [31:1] as given in the table above. The LSB of the SFADR field is used to select the appropriate bits of both flash devices to combine the byte corresponding to the selected address.

30.3.5 AHB Bus Register Memory Map Descriptions

This chapter contains definitions of registers in the AMBA address space.

30.3.5.1 AHB Bus Access Considerations

It has to be noted that all logic in the QuadSPI module implementing the AHB Bus access is designed to read the content of an external serial flash device. Therefore the following restrictions apply to the QuadSPI module with respect to accesses to the AHB bus:

- Any write access is answered with the ERROR condition according to the AMBA AHB Specification. No write occurs.
- Any AHB Command resulting in the assertion of the QSPI_FR[ABSEF] flag is answered with the ERROR condition according to the AMBA_AHB specification. The resulting AHB Command is ignored.
- AHB Bus access types fully supported are NONSEQ and BUSY.
- AHB access type SEQ is treated in the same way like NONSEQ. Refer to the AMBA AHB Specification for further details.

30.3.5.2 Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A

Starting with address QSPI_AMBA_BASE the content of the first external serial flash devices is mapped into the address space of the device containing the QuadSPI module. Serial flash address byte address 0x0 corresponds to bus address QSPI_AMBA_BASE with increasing order. Assuming that a dual-die flash is connected on the first set of external pads, the address space is divided into two parts, one for each device of the dual die package. Refer to the following table for the address mapping. The byte ordering for 32 bit access is given in Table 30-429 and for 64 bit read access the byte ordering is given in Table 30-434.

Table 30-388. Memory Mapped Individual Flash Mode - Flash A Address Scheme

<table>
<tr><th>Memory Mapped Address 32 Bit Access</th><th>Memory Mapped Address 64 Bit Access</th><th>Serial Flash Byte Address</th><th>Flash Device</th></tr>
<tr><td>QSPI_AMBA_BASE + 0x00</td><td rowspan="2">QSPI_AMBA_BASE + 0x00</td><td>0x00_0000 to 0x00_0003</td><td rowspan="5">A1</td></tr>
<tr><td>QSPI_AMBA_BASE + 0x04</td><td>0x00_0004 to 0x00_0007</td></tr>
<tr><td>…</td><td>…</td><td>…</td></tr>
<tr><td>TOP_ADDR_MEMA1 - 0x08</td><td rowspan="2">TOP_ADDR_MEMA1 - 0x08</td><td>(TOP_ADDR_MEMA1- 0x08) to (TOP_ADDR_MEMA1 - 0x04 -0x01)</td></tr>
<tr><td>TOP_ADDR_MEMA1 - 0x04</td><td>(TOP_ADDR_MEMA1 - 0x04) to (TOP_ADDR_MEMA1 - 0x01)</td></tr>
<tr><td>TOP_ADDR_MEMA1 + 0x00</td><td rowspan="2">TOP_ADDR_MEMA1 + 0x00_0000</td><td>0x00_0000 to 0x00_0003</td><td rowspan="5">A2</td></tr>
<tr><td>TOP_ADDR_MEMA1 + 0x04</td><td>0x00_0004 to 0x00_0007</td></tr>
<tr><td>…..</td><td>…</td><td>…</td></tr>
<tr><td>TOP_ADDR_MEMA2 - 0x08</td><td rowspan="2">TOP_ADDR_MEMA2 - 0x08</td><td>(TOP_ADDR_MEMA2 - 0x08) to (TOP_ADDR_MEMA2 - 0x04 - 0x01)</td></tr>
<tr><td>TOP_ADDR_MEMA2 - 0x04</td><td>(TOP_ADDR_MEMA2 - 0x04) to (TOP_ADDR_MEMA2 - 0x01)</td></tr>
</table>

The available address range depends from the size of the external serial flash device. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to Flash Read.

30.3.5.3 Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B

Starting with address TOP_ADDR_MEMA2 the content of the first external serial flash devices is mapped into the address space of the device containing the QuadSPI module. Serial flash address byte address 0x0 corresponds to bus address TOP_ADDR_MEMA2 with increasing order. Assuming that a dual-die flash is connected on the first set of external pads, the address space is divided into two parts, one for each device of the dual die package. Refer the following table for the address mapping. The byte ordering for 32 bit access is given in Table 30-429 and for 64 bit read access the byte ordering is given in Table 30-434.

Table 30-389. Memory Mapped Individual Flash Mode - Flash B Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash Byte Address	Flash Device
TOP_ADDR_MEMA2 + 0x00	TOP_ADDR_MEMA2 + 0x00	0x00_0000 to 0x00_0003	B1
TOP_ADDR_MEMA2 + 0x04		0x00_0004 to 0x00_0007	
…	…	…	
TOP_ADDR_MEMB1 - 0x08	TOP_ADDR_MEMB1 - 0x08	(TOP_ADDR_MEMB1- TOP_ADDR_MEMA2 - 0x08) to (TOP_ADDR_MEMB1 - TOP_ADDR_MEMA2 - 0x04 -0x01)	
TOP_ADDR_MEMB1 - 0x04		(TOP_ADDR_MEMB1- TOP_ADDR_MEMA2 - 0x04) to (TOP_ADDR_MEMB1- TOP_ADDR_MEMA2- 0x01)	
TOP_ADDR_MEMB1 + 0x00	TOP_ADDR_MEMB1 + 0x00_0000	0x00_0000 to 0x00_0003	B2
TOP_ADDR_MEMB1 + 0x04		0x00_0004 to 0x00_0007	
…..	…	…	
TOP_ADDR_MEMB2 - 0x08	TOP_ADDR_MEMA2 - 0x08	(TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1- 0x08) to (TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x04 - 0x01)	
TOP_ADDR_MEMB2 - 0x04		(TOP_ADDR_MEMB2- TOP_ADDR_MEMB1 - 0x04) to (TOP_ADDR_MEMB2 - TOP_ADDR_MEMB1 - 0x01)	

The available address range depends from the size of the external serial flash device. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to Flash Read.

30.3.5.4 Parallel Flash Mode

Any of the AHB flexible-buffers can be configured to work in parallel flash mode by programming the QSPI_BFGENCR[PAR_EN] bit to '1'. When parallel mode is set, Flash A1 is paired with Flash B1 and Flash A2 is paired with Flash B2. In parallel mode, software should ensure that the size of Flash A1(A2) is equal to the size of Flash B1(B2).

Reads from any even AHB bus address provides bits [7:4] of both serial flash devices and reads from any odd AHB bus address provides bits [3:0] of both flash devices. Refer to the following table for the address mapping. The byte ordering for 32 bit access is given in Table 30-431 and for 64 bit read access the byte ordering is given in Table 30-434.

Table 30-390. Memory Mapped Parallel Flash Mode Address Scheme

Memory Mapped Address 32 Bit Access	Memory Mapped Address 64 Bit Access	Serial Flash A Byte Address	Serial Flash B Byte Address
QSPI_AMBA_BASE + 0x0000_0000	QSPI_AMBA_BASE + 0x00 For details, please refer to Parallel mode and Dual Die Flashes.	0x00_0000 - 0x00_0001	0x00_0000 - 0x00_0001
QSPI_AMBA_BASE + 0x0000_0004		0x00_002 - 0x00_0003	0x00_0002 - 0x00_0003
QSPI_AMBA_BASE + 0x0000_0008	QSPI_AMBA_BASE + 0x08	0x00_0004 - 0x00_0005	0x00_0004 - 0x00_0005
QSPI_AMBA_BASE + 0x0000_000C		0x00_0006 - 0x00_0007	0x00_0006 - 0x00_0007
…	…	…	…
TOP_ADDR_MEMB2 - 0x08	TOP_ADDR_MEMB2 - 0x08	(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x08)/2	(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x08)/2
TOP_ADDR_MEMB2 - 0x04		(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE - 0x04)/2 +0x01	(TOP_ADDR_MEMB2 - QSPI_AMBA_BASE- 0x04)/2 + 0x01

The available address range covers 27 address bits, corresponding to 128 MB per flash device. The usable space depends from the size of the external serial flash devices. Any access beyond the size of the external serial flash provides undefined results.

For details concerning the read process refer to Flash Read.

30.3.5.5 AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)

30.3.5.5.1 AHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31)

memory map

207C	AHB RX Data Buffer register (ARDB 31)	32	R/W	0000_0000h	30.3551.1/ 1247

30.3551.1 AHB RX Data Buffer register (ARDB*n*)

The AHB RX Data Buffer register 0 to 31 can be used to read the buffer content of the RX Buffer from successive addresses. QSPI_ARDB0 corresponds to the RX Buffer register entry corresponding to the current value of the read pointer with increasing order.

The increment of the read pointer depends from the access scheme (DMA or flag-driven). Refer to "Data Transfer from the QuadSPI Module Internal Buffers" section in Flash Read section, RX Buffer, data read via register interface and AHB read, for the description of successive accesses to the RX Buffer content. Refer also to Byte Ordering of Serial Flash Read Data for the byte ordering scheme.

Valid address range accessible in the QSPI_ARDBn range depends from the number of RX Buffer entries implemented and from the number of valid buffer entries available in the RX Buffer.

- Example 1, RX Buffer filled completely with 32 words: In this case the address range for valid read access extends from QSPI_ARDB0 to QSPI_ARDB31.
- Example 2, RX Buffer filled with 5 valid words, RX Buffer fill level QSPI_RBSR[RDBFL] is 5. In this case an access to QSPI_ARDB4 provides the last valid entry.

Address: 0h base + 2000h offset + (4d × i), where i=0d to 31d

Bit	31–0
R W	ARXD
Reset	

ARDB*n* field descriptions

Field	Description
31–0 ARXD	ARDB provided RX Buffer Data. Byte order (endianess) is identical to the RX Buffer Data Registers.

30.4 Interrupt Signals

The interrupt request lines of the QuadSPI module are mapped to the internal flags according to the following table.

Table 30-425. Assignment of Interrupt Request Lines

IRQ/DMA line	QSPI_FR Flag	Interrupt Description
ipi_int_tfff	TBFF	TX Buffer Fill
ipi_int_tcf	TFF	Peripheral Command Transaction Finished
ipi_int_rfdf	RBDF	RX Buffer Drain
ipi_int_overrun		Buffer Overflow/Underrun Error Logical OR from:
	RBOF	RX Buffer Overrun
	TBUF	TX Buffer Underrun
	ABOF	AHB Buffer Overflow
ipi_int_cerr		Serial Flash Command Error Logical OR from:
	IPAEF	Peripheral access while AHB busy Error
	IPIEF	Peripheral Command could not be triggered Error
	IPGEF	Peripheral access while AHB Grant Error
	IUEF	Peripheral Command Usage Error
	AITEF	AHB Illegal trasaction

Table continues on the next page...

Table 30-425. Assignment of Interrupt Request Lines (continued)

IRQ/DMA line	QSPI_FR Flag	Interrupt Description
ipi_int_ored	DLPFF, TBFF, TFF, ILLINE, RBDF, RBOF, TBUF, ABSEF, ABOF, IPAEF, IPIEF, IPGEF, IUEF, AITEF	Logical OR from all the QSPI_FR flags mentioned

30.5 Functional Description

This section provides the functional information of the QuadSPI module.

30.5.1 Serial Flash Access Schemes

The Quad Serial Peripheral Interface (QuadSPI) block acts as an interface to one single or two external serial flash devices, each with up to 4 bidirectional data lines. Depending from the serial flash devices attached to the QuadSPI module the following access schemes are possible:

Table 30-426. Access Schemes for Serial Flash Data Access

Access Scheme	One Flash Device on Port A	One Flash Device on Port B	Two identical Flash Devices connected on Port A and Port B
Individual Flash Mode: Access to Flash A	**Yes**	**N/a**	**Yes**
Individual Flash Mode: Access to Flash B	**N/a**	**Yes**	**Yes**
Parallel Flash Mode: Read from Flash A and Flash B	**N/a**	**N/a**	**Yes**

Note

If two flash devices are accessed in Parallel Flash Mode, they are accessed with identical control signals. Special alignment on per-flash basis is **not** possible. It is within the responsibility of the application to ensure that the identical signals are applicable to both flash devices.

In Parallel Flash Mode, both external serial flash devices appear logically as one single memory doubled in size with respect to one individual flash device.

If two different flash devices are attached, they can be operated only in Individual Flash Mode.

In the Parallel Flash Mode, only data read commands and write command (in x1 mode) are supported. Any other IP Command will result in an error condition signaled by the assertion of the QSPI_FR[IUEF] flag and any other AHB Command will result in the assertion of the QSPI_FR[ABSEF] flag.

In the Individual Flash Mode, all supported commands are available.

Unless explicitly noted, all the following descriptions relate to the Individual Flash Mode.

30.5.2 Modes of Operation

Refer to QuadSPI Modes of Operation for an overview over the possible operational modes of the QuadSPI block.

- Normal Mode can be used for write or read accesses to an external serial flash device.
  - Serial Flash Write: Data can be programmed into the flash via the IP interface only. Refer to Flash Programming for further details.
  - Serial Flash Read: Read the contents of the serial flash device. Two separate read channels are available via RX Buffer and AHB Buffer, see Flash Read.
- Stop Mode: The mode is used for power management. When a request is made to enter Stop Mode, the QuadSPI block acknowledges the request and completes the SFM Command in progress, then the system clocks to the QuadSPI block may be shut off
- Module Disable Mode: The mode is used for power management. The clock to the non-memory mapped logic in the QuadSPI can be stopped while in Module Disable Mode. The module enters the mode by setting QSPI_MCR[MDIS].

30.5.3 Normal Mode

This mode is used to allow communication with an external serial flash device. Compared to the standard SPI protocol, this communication method uses up to 4 bidirectional data lines operating at high data rates. The communication to the external serial flash device consists of an instruction code and optional address, mode, dummy

and data transfers. The flexible programmable core engine described below is immune to a wide variety of command/protocol differences in the serial flash devices provided by various flash vendors.

30.5.3.1 Programmable Sequence Engine

The core of the QuadSPI module is a programmable sequence engine that works on "instruction-operand" pairs. The core controller executes each programmed instruction sequentially. The complete list of instructions and the corresponding operands is given in the following table.

Table 30-427. Instruction set

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
CMD	6'd1	N=2'd{0,1,2,3} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads 2'd3- Eight pads	8 bit command value	Provide the serial flash with operand on the number of pads specified
ADDR	6'd2		Number of address bits to be sent (e.g 8'd24 => 24 address bits required)	Provide the serial flash with address cycles according to the operand on the number of pads specified. The actual address to be provided will be derived from the incoming address in case of AHB initiated transactions and the value of SFAR in case of IPS initiated transactions.
DUMMY	6'd3		Number of dummy clock cycles (should be <= 64 cycles)	Provide the serial flash with dummy cycles as per the operand. The PAD information defines the number of pads in input mode. (e.g one pad implies that pad 1 is not driven, rest all are driven)
MODE	6'd4		8 bit mode value	Provide the serial flash with 8 bit operand on the number of pads specified
MODE2	6'd5	N=2'd{0,1}	2 bit mode value	Provide the serial flash with 2 bit operand on the number of pads[1] specified

Table continues on the next page...

Table 30-427. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
MODE4	6'd6	N=2'd{0,1,2}	4 bit mode value	Provide the serial flash with 4 bit operand on the number of pads[2] specified
READ	6'd7	N=2'd{0,1,2,3} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads 2'd3- Eight pads	Read data size in bytes. (For AHB transactions the user's application should ensure that data size is a multiple of 8 bytes)	Read data from flash on the number of pads specified. The data size may be overwritten by writing to the ADATSZ field of the QSPI_BUFxCR registers for AHB initiated transactions and IDATSZ field of IP Configuration Register (QuadSPI_IPCR) for IP initiated transactions.
WRITE	6'd8		Write data size in bytes	Write data on number of pads sepcified. The data size may be overwritten by writing to the IDATSZ field of IP Configuration Register (QuadSPI_IPCR) register
JMP_ON_CS	6'd9	NA	Instruction number	Every time the CS is deasserted, jump to the instruction pointed to by the operand. This instruction allows the programmer to specify the behavior of the controller when a new read transaction is initiated following a CS deassertion.

Table continues on the next page...

Table 30-427. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
ADDR_DDR	6'd10	N=2'd{0,1,2,3} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads 2'd3- Eight pads	Number of address bits to be sent (e.g 8'd24 => 24 address bits required)	Provide the serial flash with address cycles according to the operand on the number of pads sepcified at each clock edge of serial flash clock. The actual address to be provided will be derived from the incoming address in case of AHB initiated transactions and the value of QSPI_SFAR in case of IPS initiated transactions.
MODE_DDR	6'd11		8 bit mode value	Provide the serial flash with 8 bit operand on the number of pads specified at each clock edge of serial flash.
MODE2_DDR	6'd12	N=2'd{0}	2 bit mode value	Provide the serial flash with 2 bit operand on the number of pads specified at each clock edge of serial flash[3]
MODE4_DDR	6'd13	N=2'd{0,1}	4 bit mode value	Provide the serial flash with 4 bit operand on the number of pads specified at each clock edge of serial flash[4].

Table continues on the next page...

Table 30-427. Instruction set (continued)

Instruction	Instruction encoding	Pins	Operand	Action on Serial Flash(es)
READ_DDR	6'd14	N=2'd{0,1, 2,3} 2'd0 - One pad 2'd1 - Two pads 2'd2 - Four pads 2'd3- Eight pads	Read data size in bytes. (For AHB transactions the user's application should ensure that data size is in multiple of 8 bytes)	Read data from flash on the number of pads specified at each clock edge of serial flash. The data size may be overwritten by writing to the ADATSZ field of the QSPI_BUFxCR registers for AHB initiated transactions and IDATSZ field of IP Configuration Register (QuadSPI_IPCR) for IP initiated transactions
WRITE_DDR	6'd15		Write data size in bytes	Write data on the number of pads specified at each clock edge of serial flash. The data size may be overwritten by writing to the IDATSZ field of IP Configuration Register (QuadSPI_IPCR) register
DATA_LEARN	6'd16		8 bit Data learning pattern	Find the correct sampling point with the data learning pattern. When this instruction is encountered, the QSPI_SMPR[DDRSMP] values are ignored and the controller finds the correct sampling point on its own by sampling the data learning pattern.[5]
STOP	8'd0	NA	NA	Stop execution; deassert CS

1. For a one pad instruction, MODE2 will take 2 serial flash clock cycles on the flash interface.
2. For a one pad instruction, MODE4 will take 4 serial flash clock cycles on the flash interface. For a 4 pad instruction, MODE4 will take 1 serial flash clock cycle on the flash interface.
3. For a one pad instruction, MODE2_DDR will take 1 serial flash clock cycle on the flash interface.
4. For a one pad instruction, MODE4_DDR will take 2 serial flash clock cycles on the flash interface. For a 4 pad instruction MODE4_DDR will take half a cycle on the serial flash interface.
5. It is not recommended to have 0x00 or 0xFF as the data learning pattern.

A sequence of such instruction-operand pairs may be pre-populated in the LUT according to the device connected on board. Each instruction-operand pair is of 16 bits (2 bytes) each. Every sequence pre-programmed in the LUT is referred to by its index.

The programmable sequence engine allows the user to configure the QuadSPI module according to the serial flash connected on board. The flexible structure is easily adaptable to new command/protocol changes from different vendors.

30.5.3.2 Flexible AHB buffers

In order to reduce the latency of the reads for AHB masters, the data read from the serial flash is buffered in flexible AHB buffers. There are four such flexible buffers. The size of each of these buffers is configurable with the minimum size being 0 Bytes and maximum size being the size of the complete buffer instantiated.The size of buffer 0 is defined as being from 0 to QSPI_BUF0IND. The Size of buffer 1 is from QSPI_BUF0IND to QSPI_BUF1IND, buffer2 is from QSPI_BUF1IND to QSPI_BUF2IND and buffer 3 is from QSPI_BUF2IND to the size of the complete buffer, which is given in the Chip Configuration Chapter.

Each flexible AHB buffer is associated with the following

1. An AHB master. Optionally, buffer3 may be configured as an "all master" buffer by setting the QSPI_BUF3CR[ALLMST] bit. When buffer3 is configured in such a way, any access from a master not associated with any other buffer is routed to buffer3.
2. A datasize field representing the amount of data to be fetched from the flash on every "missed" access.

The master port number of every incoming request is checked and the data is returned/fetched into the corresponding associated buffer. Every "missed" access to the buffer causes the controller to clear the buffer and fetch QSPI_BUFxCR[ADATSZ] amount of data from the serial flash.As such, there is no benefit in configuring a buffer size of greater than ADATSZ, as the locations greater than ADATSZ will never be used. For any AHB access, the sequence pointed to by the QSPI_BFGENCR[SEQID] field is used for the flash transaction initiated. The data is returned to the master as soon as the requested amount is read from the serial flash. The controller however, continues to prefetch the rest of the data in anticipation of a next consecutive request. Figure 30-414 shows the flexible AHB buffers.

The QSPI_BFGENCR[SEQID] field points to an index of the LUT. Refer to Look-up Table for details.

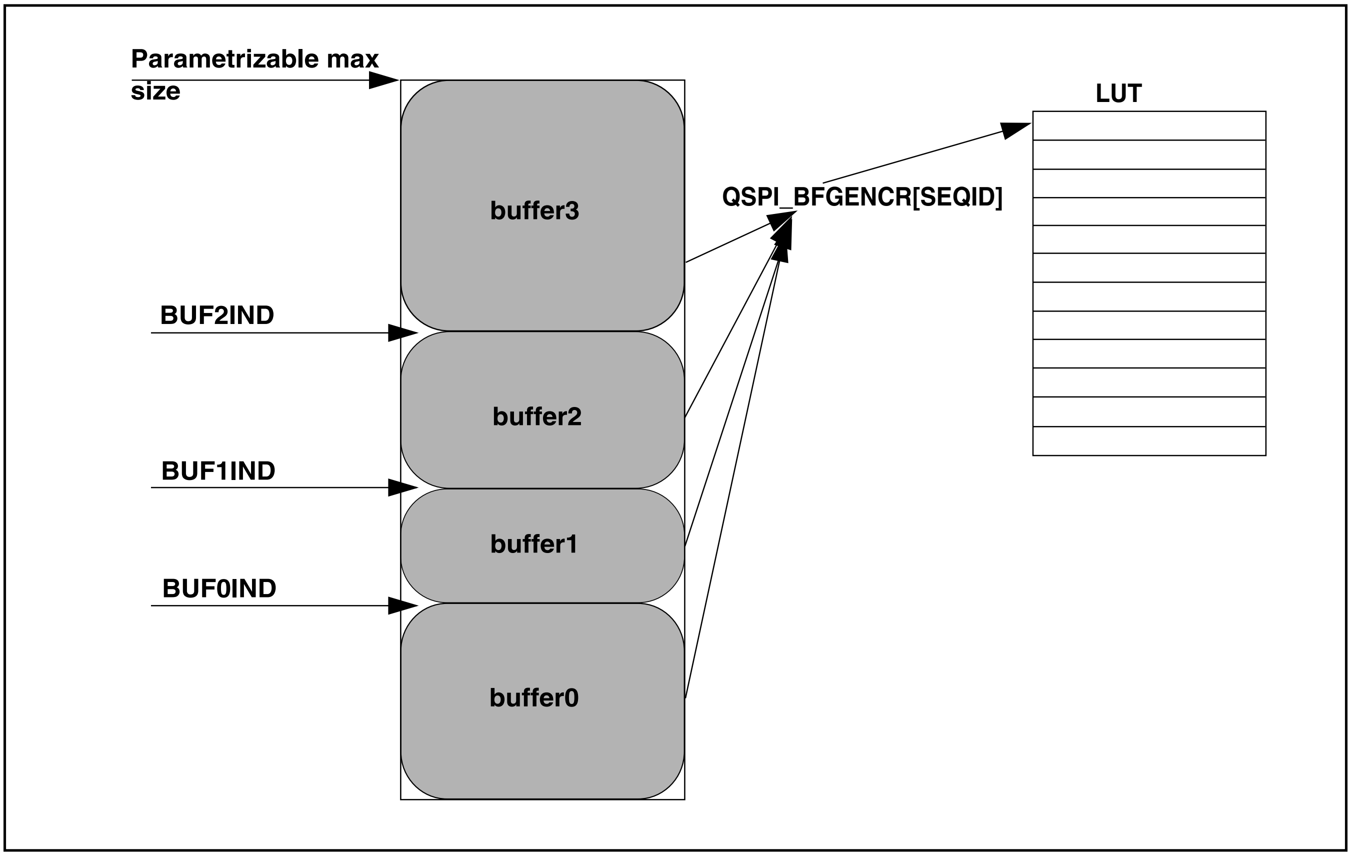

Figure 30-414. Flexible AHB Buffers

Buffer0 may optionally be configured to be associated with a high priority master by setting the QSPU_BUF0CR[HP_EN] bit. An access by a high priority master suspends any ongoing prefetch to any of the other buffers. The ongoing prefetch is suspended and the high priority master is serviced first. Once the high priority masters access completes, the suspended transaction is resumed (before any other AHB access is entertained). The status of the suspended buffer can be read from Sequence Suspend Status Register (QuadSPI_SPNDST).

30.5.3.3 Suspend-Abort Mechanism

Any low priority AHB access can be suspended by a high priority AHB master request. The ongoing transaction is suspended at 64 bit boundary. The suspended transaction is restarted after the high priority master is served and the high priority transaction including data prefetch is completed. While a transaction is in suspended state, it may be aborted if a transaction by the same suspended master is made to a location which is different from the location of the suspended transaction.

Any ongoing transaction is aborted if a request from the same master arrives for a location other than the location at which the transaction is going on. The abort can happen at any point of time.

30.5.3.4 HBURST Support

QuadSPI controller supports HBURST and HSIZE on the AHB interface. HBURST indicates if the transfer forms part of a burst. Four, eight and sixteen beat bursts are supported and the burst may be either incrementing or wrapping. HSIZE indicates the size of the transfer. 8, 16, 32 and 64 bit data size are supported. In case of WRAP accesses, QuadSPI generates aligned accesses to Serial Flash if there is no buffer hit for any incoming non-sequential AHB access. In case there is a buffer hit, the incoming address in the haddr line is latched as it is. If the total burst size is more than the data prefetch size an error response is generated and QSPI_FR[AIBSEF] is set. The data perfetch size can be defined by QSPI_BUFxCR[ADATSZ] or data size mentioned in the sequence pointed to by the SEQID field when ADATSZ is programmed as zero. A few examples are shown in the figure below:

HADDR = 0x38
HBUST = WRAP4
HSIZE = 64 bits
Flash xsaction start = 0x20
Incoming AHB access= 0x38, 0x20, 0x28, 0x30

HADDR = 0x38
HBUST = INCR4
HSIZE = 64 bits
Flash xsaction start = 0x38
Incoming AHB access= 0x38, 0x40, 0x48, 0x50

HADDR = 0x50
HBUST = WRAP8
HSIZE = 64 bits
Flash xsaction start = 0x40
Incoming AHB access= 0x50, 0x58, 0x60, 0x68, 0x70, 0x78, 0x40, 0x48

HADDR = 0xD0
HBUST = WRAP16
HSIZE = 64 bits
Flash xsaction start = 0x80
Incoming AHB access= 0xD0, 0xD8, 0xE0, ...0xF8, 0x80, 0x88, ... 0xC8

HADDR = 0xD4
HBUST = WRAP8
HSIZE = 32bits
Flash xsaction start = 0xC0
Incoming AHB access= 0xD4, 0xD8, 0xDC, 0xC0, 0xC4, 0xC8,0xCC, 0xD0

HADDR = 0x54
HBUST = INCR8
HSIZE = 32bits
Flash xsaction start = 0x54
Incoming AHB access= 0x54, 0x58, 0x5C, 0x60, 0x64, 0x68,0x6C, 0x70

Figure 30-415. QuadSPI HBURST support

NOTE

The software must take care that the prefetch size should never be set less than the minimum data needed by any external interface to start processing.

30.5.3.5 Look-up Table

The Look-up-table or LUT consists of a number of pre-programmed sequences. Each sequence is basically a sequence of instruction-operand pairs which when executed sequentially generates a valid serial flash transaction. Each sequence can have a maximum of 8 instruction-operand pairs. The LUT can hold a maximum of 16 sequences. The figure below shows the basic structure of the sequence in the LUT.

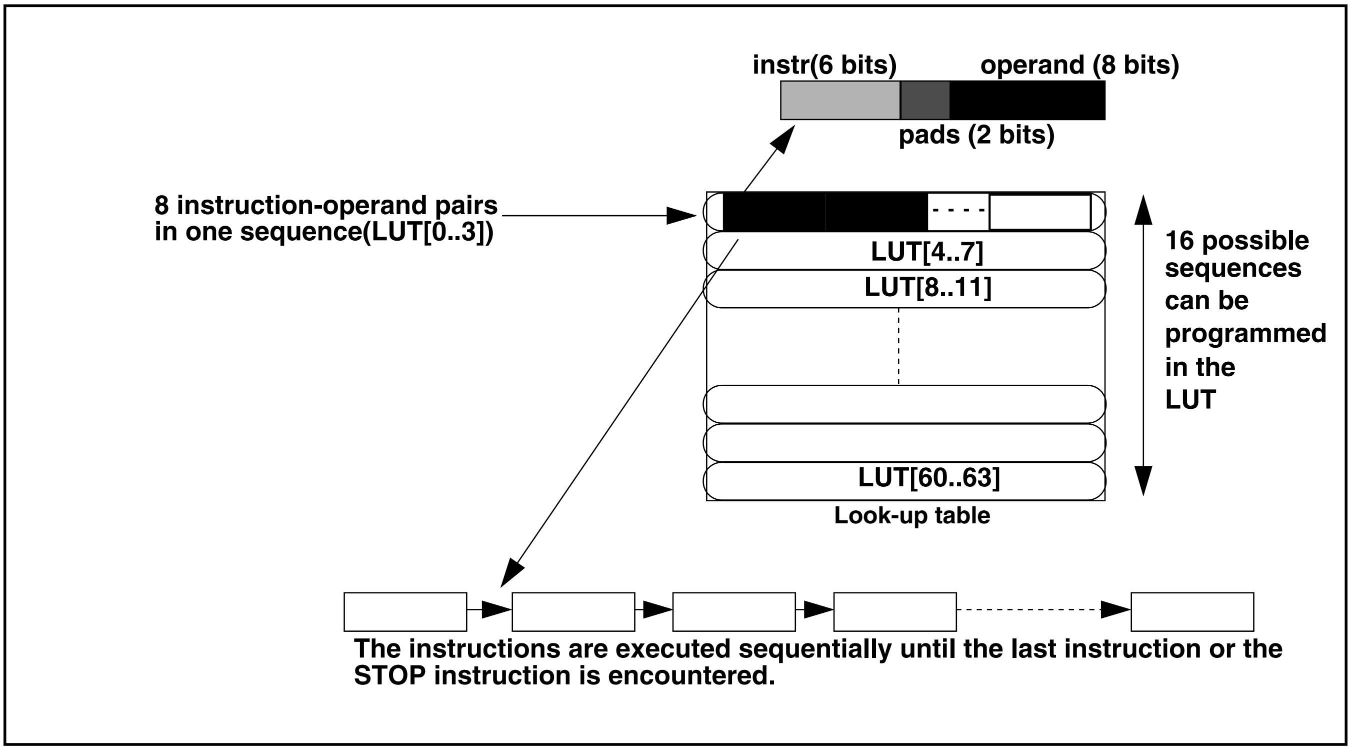

Figure 30-416. LUT and sequence structure

At reset, the index 0 of the look-up-table (LUT[0..3]) is programmed with a basic read sequence as given in Table 30-428. After reset the complete LUT may be reprogrammed according to the device connected on board.In order to protect its contents during a code runover the LUT may be locked, after which a write to the LUT will not be successful until it has been unlocked again.The key for locking or unlocking the LUT is **0x5AF05AF0**. The process for locking and un-locking the LUT is as follows:

Locking the LUT

1. Write the key **(0x5AF05AF0)** in to the LUT Key Register (QuadSPI_LUTKEY).
2. Write 0b01 to the LUT Lock Configuration Register (QuadSPI_LCKCR). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write into this register locks the LUT.

Unlocking the LUT

1. Write the key **(0x5AF05AF0)** into the LUT Key Register (QuadSPI_LUTKEY)
2. Write 0b10 to the LUT Lock Configuration Register (QuadSPI_LCKCR). Note that this IPS transaction should immediately follow the above IPS transaction (no other IPS transaction can be issued in between). A successful write into this register locks the LUT.

The lock status of the LUT can be read from QSPI_LCKCR[UNLOCK] and QSPI_LCKCR[LOCK] bit.

Some example sequences are defined in Example Sequences. The reset sequence at LUT index 0 is given in the following table.

Table 30-428. Reset sequence

Instruction	Pad	Operand	Comment
CMD	0x00	0x03	Read Data byte command on one pad
ADDR	0x00	0x18	24 Addr bits to be sent on one pad
READ	0x00	0x08	Read 64 bits
JMP_ON_CS	0x00	0x00	Jump to instruction 0 (CMD)

30.5.3.6 Issuing SFM Commands

Each access to the external device follows the same sequence:

1. The user must pre-populate the LUT with the serial flash command sequences that are required for the flash device being used.
2. The QuadSPI module starts executing the instructions in the sequence one by one. The transaction starts and the status bit QSPI_SR[BUSY] is set.
3. Communication with the external serial flash device is started and the transaction is executed.

4. When the transaction is finished (all transmit- and receive operations with the external serial flash device are finished) the status bit QSPI_SR[BUSY] is reset. In case of an IP Command the QSPI_FR[TFF] flag is asserted.

Further details are given in below in Flash Programming and Flash Read.

You can trigger the processing of SFM commands in the QuadSPI module in one of the following ways:

- **Using IP commands**

  For IP Commands the required components need to be written into the following registers:

  - Write the serial flash address to be used by the instruction into QSPI_SFAR, refer to Serial Flash Address Register (QSPI_SFAR). For IP Commands not related to specific addresses, the base address of the related flash need to be programmed.For example, for an instruction which does not require an address (i.e. write enable instruction) the SFAR should be programmed with the base address of the memory the command is to be sent to.
  - Write the sequence ID and data size details in the IP Configuration Register (QSPI_IPCR).
  - Note that the write into the QSPI_IPCR[SEQID] field must be the last step of the sequence. It is possible to combine all fields of the QSPI_IPCR into one single write. Refer to IP Configuration Register (QSPI_IPCR) for details.

  Note that there are some conditions where no IP Command is executed after writing the QSPI_IPCR[SEQID] field and the write operation itself is ignored. They are described in Command Arbitration.

- **Using AHB commands**

  Any AHB memory mapped access is routed to one of the buffers depending on the master port number of the request. If the access is a "miss", a new serial flash transaction is started. The transaction is based on the sequence pointed to by the BFGENCR[SEQID] field as described in Flexible AHB buffers.

  An AHB access is termed memory mapped when the access is to the memory mapped serial flashes, as described in Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A and Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B.

  Again the possible error conditions are described in Command Arbitration .

30.5.3.7 Flash Programming

In all cases the memory sector to be written needs to be erased first. The programming sequence itself is then initiated in the following way:

1. Check that the TX Buffer is empty. If the QSPI_SR[TXNE] bit is set then the TX Buffer must be cleared by writing 1 into the QSPI_MCR[CLR_TXF] bit.
2. Program the address related to the command in the QSPI_SFAR register.
3. Provide initial data for the program command into the circular buffer via register TX Buffer Data Register (QSPI_TBDR) . At least one word of data must be written into the TX Buffer up to a maximum of 16.
4. Program the QSPI_IPCR register to trigger the command. The QSPI_IPCR[SEQID] should point to an index of the LUT which has the flash program sequence pre-programmed.The IDATSZ field should be set to denote the size of the write.
5. Depending on the amount of data required, step 3 must be repeated until all the required data have been written into the QSPI_TBDR register.The QSPI_SR[TXFULL] can be used to check if the buffer is ready to receive more data. At any time, the QSPI_TBSR[TRCTR] field can be read to check how many words have been written actually into the TX Buffer.

Upon writing the QSPI_IPCR[SEQID] field (refer to step 4) the QuadSPI module will start to execute the programmed sequence. It is the responsibility of the software to ensure that a correct sequence is programmed into the LUT in accordance with the flash memory connected to the module. The data is fetched from the TX Buffer. It consists of **16** entries of 32-bits and is organized as a circular FIFO, whose read pointer is incremented after each fetch. When all data are transmitted, the QuadSPI module will return from 'busy' to 'idle'. However, this is not true for the external device since the internal programming is still ongoing. It is up to the user to monitor the relevant status information available from the serial flash device and to ensure that the programming is finished properly.

30.5.3.8 Flash Read

Host access to the data stored in the external serial flash device is done in two steps: First the data must be read into the internal buffers and in the second step these internal buffers can be read by the host.

1. **Reading Serial Flash Data into the QuadSPI Module Internal Buffers**

A read access to the external serial flash device can be triggered in two different ways:

- **IP Command Read**: For **reading flash data into the RX Buffer** the user must provide the correct sequence ID in the QSPI_IPCR[SEQID] register. The sequence ID points to a sequence in the LUT. It is the responsibility of the software to ensure that a correct read sequence in programmed in the LUT in accordance with the serial flash device connected on board. The user should program the Serial Flash Address Register (QSPI_SFAR) and the IP Configuration Register (QSPI_IPCR) registers. All available read commands supported by the external serial flash are possible.

  Optionally it is possible to clear the RX Buffer pointer prior to triggering the IP Command by writing a 1 into the QSPI_MCR[CLR_RXF] bit.

  From these inputs, the complete transaction is built when the QSPI_IPCR[SEQID] field is written. The transaction related to the read access starts and the requested number of bytes is fetched from the external serial flash device into the RX Buffer. Since the read access is triggered by an IP command the IP_ACC status bit and the BUSY bit are both set(both are located in the Status Register (QSPI_SR)). A count of the number of entries currently in the Rx Buffer can be obtained from QSPI_RBCT[RXBRD].

  The communication with the external serial flash is stopped when the specified number of bytes has been read (successful completion of the transaction).

- **AHB Command Read**: For **reading flash data into the AHB Buffer** the user must setup a read access by a master to the address range in the system memory map which the external serial flash devices are mapped to. The user should also program the buffer registers corresponding to the AHB master initiating the request, this is depends on the configuration of the QSPI_RBCT[RXBRD]. The user should provide the correct sequence ID into the buffer generic configuration register (QSPI_BFGENCR). It is the responsibility of the software to ensure that a correct read sequence in programmed in the LUT in accordance with the serial flash device connected on board. Flash device selection and access mode are determined by the address accessed in the AHB address space associated to the QuadSPI module, refer to Memory Mapped Serial Flash Data - Individual Flash Mode on Flash A, Memory Mapped Serial Flash Data - Individual Flash Mode on Flash B and Parallel Flash Mode.

  On each AHB read access to the memory mapped area the valid data in the AHB Buffer is checked against the address requested in the actual read. When the AHB read request can't be served from the content of the AHB Buffer, the buffer is flushed and the sequence pointed to by the sequence ID is executed by the

controller. The requested number of buffer entries defined in the QSPI_BUFxCR[ADATSZ] field is then fetched from the external serial flash device into the internal AHB Buffer. Since the read access is triggered via the AHB bus, the QSPI_SR[AHB_ACC] status bit is set driving in turn the QSPI_SR[BUSY] bit until the transaction is finished. The communication with the external serial flash is stopped when the specified number of entries has been filled.

2. **Data Transfer from the QuadSPI Module Internal Buffers**

   The data read out from the external serial flash device by the QuadSPI module is stored in the internal buffers.The means of accessing the data from the buffer differs depending on which buffer the data has been loaded to. Refer to Figure 30-1 for details about the two available buffers, the RX Buffer and the AHB Buffer, in the QuadSPI module:

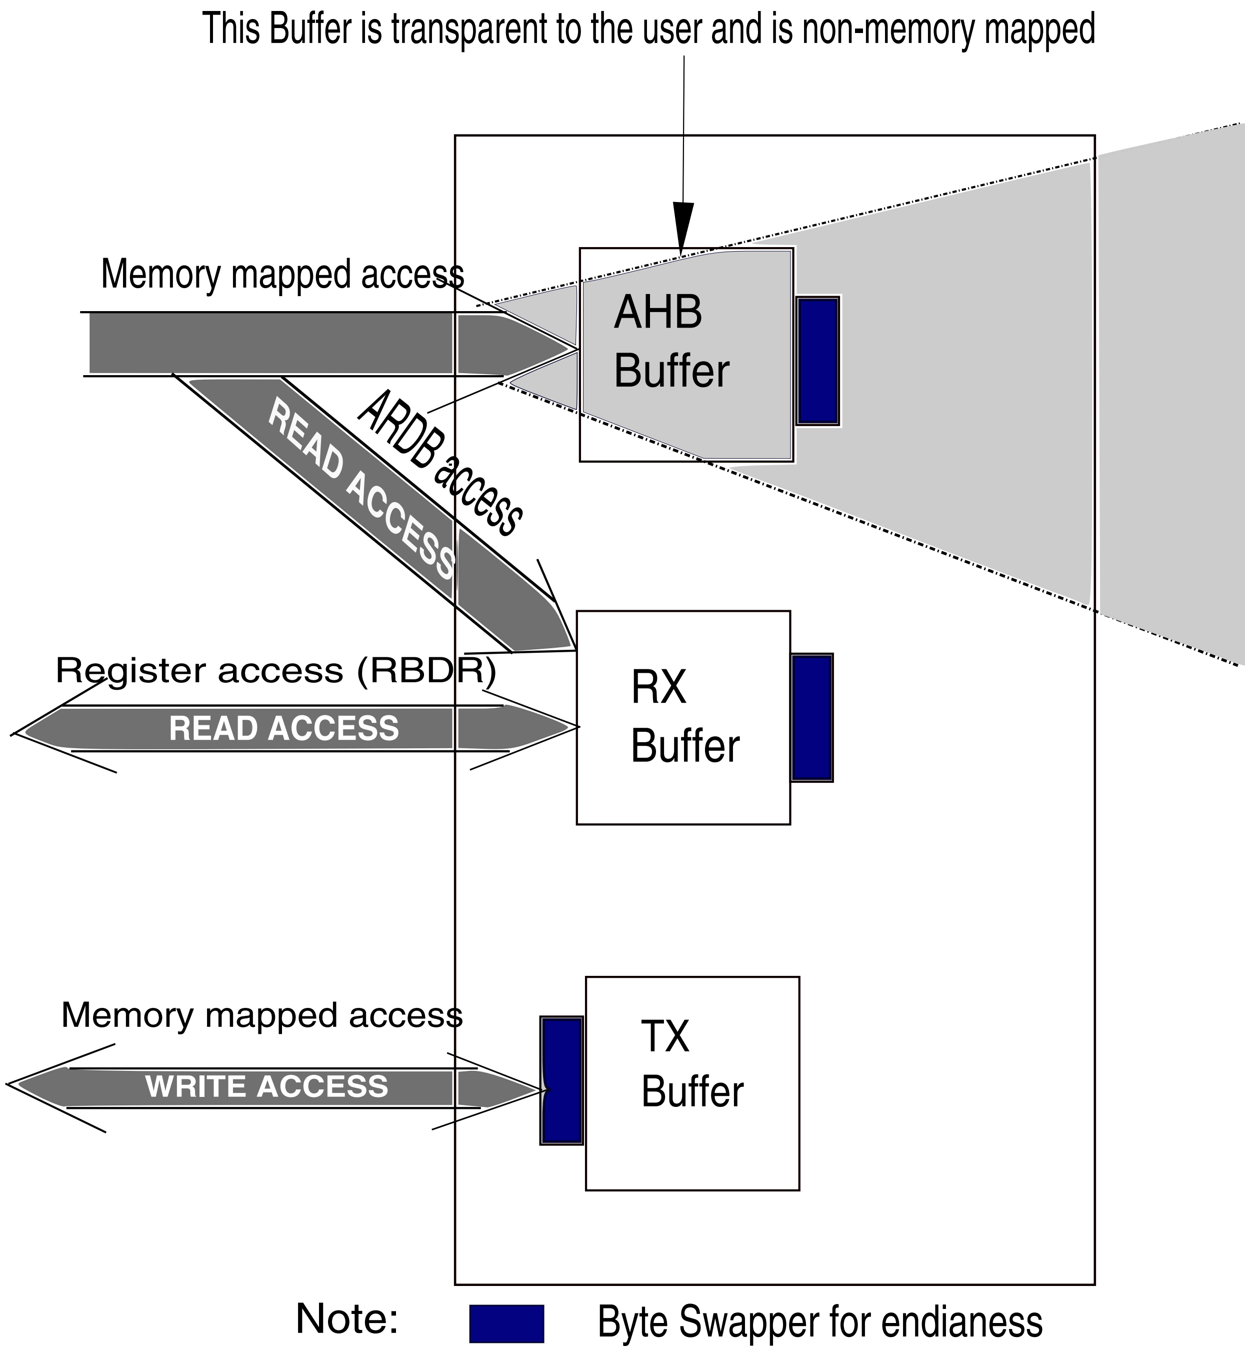

Figure 30-417. QuadSPI memory map

- The RX Buffer is implemented as FIFO of depth 32 entries of 4 bytes. Its content is accessible in two different address areas both referring to the identical data and the same physical memory.

  In the IPS address space in the area associated to QSPI_RBDR0 to QSPI_RBDR31

  In the AHB address space in the area associated to QSPI_ARDB0 to QSPI_ARDB31. Two successive entries are accessed with one single 64 bit AHB read operation.

RX Buffer operation can be summarized as follows: The QSPI_RBCT[WMRK] field determines at which fill level the RXWE bit is asserted and how many entries are removed from the RX Buffer on each Buffer POP operation. So the QSPI_SR[RXWE] bit indicates that the configured number of data entries is available in the RX Buffer and the QSPI_RBSR[RDBFL] field indicates how many valid entries are available in total. Note that the first entry (QSPI_RBDR0 or QSPI_ARDB0) always corresponds to the first valid entry in the RX Buffer. The software needs to manage the number of valid data bytes itself.

Further details can be found in RX Buffer Data Registers 0 - 31 (QSPI_RBDR0 - QSPI_RBDR31) and inAHB RX Data Buffer (QSPI_ARDB0 to QSPI_ARDB31).

- **Flag-based Data Read of the RX Buffer** is done by polling the QSPI_SR[RXWE] bit. When it is asserted the valid entries can be read either via the IPS address space (QSPI_RBDRn) or the AHB address space (QSPI_ARDBn). A Buffer POP operation must be triggered by the application by writing a 1 into the QSPI_FR[RBDF] bit - this automatically updates the FIFO to point to the next entry as defined by RBCT[WMRK]. E.g. if WMRK is set to 3, then the buffer will discard 16bytes of data.
- **DMA controlled Data Read of the RX Buffer** is done by using the DMA module.The application must ensure that the DMA controller of the related device is programmed appropriately like it is described in DMA Usage.

  DMA controlled read out is triggered fully automatically by the assertion of the QSPI_SR[RXWE] bit. The related Buffer POP operation is also handled completely inside the QuadSPI module. Like in the case above, accessing the RX Buffer content either on QSPI_RBDRn or QSPI_ARDBn related addresses is equivalent.

- **AHB Buffer data read via memory mapped access:** This kind of access is done by reading one of the addresses assigned to the external serial flash device(s) within the range given in Table 30-387 table *under the condition that the data requested are already present in the AHB Buffer or it is currently being read from the serial flash device by the instruction in progress.* If this is not the case a memory mapped AHB command read is triggered as described above. If the requested data is already available in the AHB Buffer they are provided directly to the host.

  When AHB access are made to the flash memory mapped address, the data will be fetched and returned to the AHB interface. Till the data is being fetched the AHB interface would be stalled. As soon as the data from the requested address has been read by the QuadSPI module the AHB read access is served. So it is

possible to run sequential reads from the AHB buffer at arbitrary speed without the need to monitor any information about the availability of the data. Nevertheless this access scheme stalls the AHB bus for the time required to read the data from the serial flash device. A better way is (when it is known the access is sequential) to have a prefetch enabled (by programming the ADATSZ field) such that before the next sequential AHB access come, the data is already fetched into the buffer.

As long as the host restricts its accesses to the data already in the buffer and the data currently fetched from the serial flash, it is possible to run the host read from the AHB Buffer in parallel to the serial flash read into the AHB Buffer.

30.5.3.9 Byte Ordering of Serial Flash Read Data

In this paragraph the byte ordering of the serial flash data is given. The basic scheme is that the **first** byte read out of the serial flash device - which is addressed by the QSPI_SFAR[SFADR] field - corresponds to bit position QSPI_RBDR0[31:24] register for IP Command read. In contrast to that for AHB Command read the bytes are always positioned according to the byte ordering of the AHB bus.

- **Byte Ordering in Individual Flash Mode**

  The following table gives the byte ordering scheme of how the byte oriented data space of the serial flash device is mapped into one single 32 bit entry of the RX Buffer or the AHB Buffer. The table is valid within the following context:

  - Flash A or Flash B in Individual Flash Mode
  - All AHB data read commands with access size of 32 bit

Table 30-429. Byte Ordering in Individual Flash Mode

Serial Flash Byte Numbering	3	2	1	0
Buffer Entry Bit Position [31:0] **(32 Bit data width)**	[31:24]	[23:16]	[15:8]	[7:0]

Note

For IP Commands the read size can be given in number of bytes. If this number is not a multiple of 4, then the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

For AHB Commands, reads, starting from an address not aligned to 32 bit boundaries, the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

- **Byte Ordering in Parallel Flash Mode**

  In Parallel Flash Mode each byte is combined out of 2 half bytes which are read or written in parallel from the two serial flash devices. The following tables shows how the flash content is separated into the half bytes and how the half bytes are assembled to the content of the QSPI_RBDR0 register.

Table 30-430. Serial Flash Device Half Byte Ordering

Serial Flash Device Byte #	Flash A Bit Position		Flash B Bit Position	
	[7:4]	[3:0]	[7:4]	[3:0]
0	fah0	fal0	fbh0	fbl0
1	fah1	fal1	fbh1	fbl1
2	fah2	fal2	fbh2	fbl2
3	fah3	fal3	fbh3	fbl3
4	fah4	fal4	fbh4	fbl4
5	fah5	fal5	fbh5	fbl5
6	fah6	fal6	fbh6	fbl6
7	fah7	fal7	fbh7	fbl7
8	fah8	fal8	fbh8	fbl8

The table entry naming reflects the half byte positioning in the serial flash devices:

- **<fa>**h0 means **Flash A**, <fb>h0 means Flash B.

- fa**<h>**0 means half byte in **high position**, fa<l>o means half byte in low position.
- fah**<0>** means **physical byte address 0** in the serial flash device, fal<1> means physical byte address 1 in the serial flash device.

Table 30-431. Byte Ordering in Parallel Flash Mode - RX Buffer

QSPI_SFAR[SFADR] set to 0x000_0000								
QSPI_RBDR0 **QSPI_ARDB0**	fal1	fbl1	fah1	fbh1	fal0	fbl0	fah0	fbh0
QSPI_RBDR1 **QSPI_ARDB1**	fal3	fbl3	fah3	fbh3	fal2	fbl2	fah2	fbh2
QSPI_SFAR[SFADR] set to 0x000_0001								
QSPI_RBDR0 **QSPI_ARDB0**	fal2	fbl2	fah2	fbh2	fal1	fbl1	fah1	fbh1
QSPI_RBDR1 **QSPI_ARDB1**	fal4	fbl4	fah4	fbh4	fal3	fbl3	fah3	fbh3

Note

For IP Commands the read size can be given in number of bytes. If this number is not a multiple of 4 the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

Table 30-432. Byte Ordering in Parallel Flash Mode - TX Buffer*

QSPI_SFAR[SFADR] set to 0x000_0000								
QSPI_TBDR0	fal1	fbl1	fah1	fbh1	fal0	fbl0	fah0	fbh0
QSPI_TBDR1	fal3	fbl3	fah3	fbh3	fal2	fbl2	fah2	fbh2

* Appicable only for single io mode.

Table 30-433. Byte Ordering in Parallel Flash Mode - AHB Buffer

AHB Address **(32 Bit Access)**	fal1	fbl1	fah1	fbh1	fal0	fbl0	fah0	fbh0
AHB Address 0x800_0004 **(32 Bit Access)**	fal3	fbl3	fah3	fbh3	fal2	fbl2	fah2	fbh2

Note

For AHB Command read starting from an address not aligned to 32 bit boundaries or AHB access size smaller than 32 bit the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

- **Buffer Entry Ordering for 64 Bit Read Access**

  For read access via the AHB interface 64 bit access is possible. Each 64 bit access reads 2 32 bit entries simultaneously. The ordering of these 32 bit entries within the 64 bit word is given in the following table.

Table 30-434. 64 Bit Read Access Buffer Entry Ordering

AHB Read Data Bit Position [63:0]	[63:32]	[31:0]
Buffer Entry #	**Odd (1, 3, 5, ...)**	**Even (0, 2, 4, ...)**

30.5.3.10 Normal Mode Interrupt and DMA Requests

The QuadSPI module has 13 different flags that can only generate interrupt requests and one flag that can generate interrupt as well as DMA requests. The following table lists the eight conditions. Note that the flags mentioned in the table are related to the Flag Register (QSPI_FR).

Table 30-435. Interrupt and DMA Request Conditions

Condition	Flag(QSPI_SPISR)	DMA
Data Learn patttern Failure	DLPFF	-
TX Buffer Fill	TBFF	-
TX Buffer Underrun	TBUF	-

Table continues on the next page...

Table 30-435. Interrupt and DMA Request Conditions (continued)

Condition	Flag(QSPI_SPISR)	DMA
Illegal Instruction Error	ILLINE	-
RX Buffer Drain	RBDF	X
RX Buffer Overflow	RBOF	-
AHB Buffer Overflow	ABOF	-
AHB Sequence Error	ABSEF	-
AHB Illegal Transaction Error	AITEF	-
IP Command Usage Error	IUEF	-
IP Command Trigger during AHB Access Error	IPAEF	-
IP Command Trigger could not be executed Error	IPIEF	-
IP Access during AHB Grant Error	IPGEF	-
IP Command related Transaction Finished	TFF	-

Each condition has a flag bit in the Flag Register (QSPI_FR) and a Request Enable bit in the DMA Request Select and Enable Register (QSPI_RSER) . The RX Buffer Drain Flag (RBDF) has separate enable bits for generating IRQ and DMA requests. Note that not all flags have an individual IRQ line. Check the devices Interrupt Vector Table for more details.

- Transmit Buffer Fill Interrupt Request:

  The Transmit Buffer Fill IRQ indicates that the TX Buffer can accept new data. It is asserted if the QSPI_FR[TBFF] flag is asserted and if the corresponding enable bit (QSIP_RSER[TBFIE]) is set. Refer to TX Buffer Operation, for details about the assertion of the QSPI_FR[TBFF] flag.

- Receive Buffer Drain Interrupt or DMA Request:

  The Receive Buffer Drain IRQ derived from the QSPI_FR[RBDF] flag indicates that the RX Buffer of the QuadSPI module has data available from the serial flash device to be read by the host. It remains set as long as the QSPI_RBSR[RXWE] bit is set. The QSPI_RSER[RBDIE] bit enables the related IRQ.

  Aside from the IRQ it is possible to handle RX Buffer drain by DMA. If the QSPI_RSER[RBDDE] bit is set, a DMA request will be triggered when the RX Buffer contains more than QSPI_RBCT[WMRK] valid entries.The application must set the environment appropriately (e.g. the DMA controller) for the DMA transfers.

- Buffer Overflow/Underrun Interrupt Request:

The Buffer Overflow/Underrun IRQ is a combination of the following flags (all located in the QSPI_FR register with the related enable bits in the QSPI_RSER register):

- TBUF - TX Buffer Underrun, enabled by TBUIE
- RBOF - RX Buffer Overflow, enabled by RBOIE
- ABOF - AHB Buffer Overflow, enabled by ABOIE

  The Transmit Buffer Underrun indicates that an underrun condition in the TX Buffer has occurred. It is generated when a write instruction is triggered whilst the Tx Buffer is empty and the QSPI_RSER[TFUFIE] bit is set.

  The Receive Buffer Overflow indicates that an overflow condition in the RX Buffer has occurred. It is generated when the RX Buffer is full, an additional read transfer attempts to write into the RX Buffer and the QSPI_RSER[RBOIE] bit is set.

  The AHB Buffer Overflow indicates that an overflow condition in the AHB Buffer has occurred. It is generated when the AHB Buffer is full, an additional read transfer attempts to write into the AHB Buffer and the QSPI_RSER[ABOIE] bit is set.

  The data from the transfers that generated the individual overflow conditions is ignored.

- Serial Flash Command Error Interrupt Request

  If the IPAEF, IPIEF, IPGEF, ABSEF or IUEF flags in the QSPI_SR are set, and the related interrupt enable bits in the QSPI_RSER are also set, then an interrupt is requested.

- Transaction Finished Interrupt Request

  The IP Command Transaction Finished IRQ indicates the completion of the current IP Command.It is triggered by the QSPI_FR[TFF] flag and is masked by the QSPI_RSER[TFIE] bit.

30.5.3.11 TX Buffer Operation

The TX Buffer provides the data used for page programming. For proper operation it is required to provide at least one entry in the TX Buffer prior to starting the execution of the page programming command. The application must ensure that the required number of data bytes is written into the TX Buffer fast enough as long as the command is executed without a TX Buffer overflow or underrun.

The QuadSPI module sets the QSPI_FR[TBFF] flag so long as the TX Buffer is not full and can accept more data.

When the QuadSPI module tries to pull data out of an empty TX Buffer the TX Buffer underrun is signaled by the QSPI_FR[TBUF] flag. The current IP Command leading to the underrun condition is continued until the specified number of bytes has been sent to the serial flash device, in the underrun condition, the data transferred is undefined i.e. once the underrun flag is set, it will return the garbage value until the required number of bytes are not sent. When this Sequence Command is finished, the QSPI_FR[TBFF] flag is asserted indicating that the Tx Buffer is ready to be written again.

The TX Buffer overflow isn't signaled explicitly, but the TX Buffer fill level can be monitored by the QSPI_TBSR[TRBFL] field.

Refer to TX Buffer Status Register (QuadSPI_TBSR) and Flag Register (QuadSPI_FR) for details about the TX Buffer related registers.

30.5.3.12 Address scheme

Earlier serial flash memories supported only 24-bit address space hence restricting the maximum memory size of the serial flash as 16 MB. The new memory specification supports two types of 32-bit addressing mode in addition to legacy 24-bit address mode.

- **Extended Address Mode**

  In this mode, the legacy 24-bit commands are converted to accept 32-bit address commands. The flash memory needs to be configured for 32-bit address mode. Also, while programming the LUT sequence in QuadSPI for 32-bit mode, the ADDR and ADDR_DDR command should be programmed with 8’d32 as the operand value. By default, the QuadSPI is in 24-bit legacy address mode. Each of the memory vendors have a different way of enabling this mode (Refer to the memory specification from memory vendors). For example, the command B7h sent to Macronix flash will enable it for 32-bit address mode.

- **Extended Address register**

  In this mode, the upper 8-bit of the 32-bit address is provided by the Extended address register in the memory itself. The memory provides a specific register which is updated according to the address to be accessed. This effectively converts the legacy 24-bit address command into 32-bit address commands. The memories greater in size than 16 MB, consists of banks of 16 MB. The 8-bit written in the extended address register effectively enables a bank. For example in Spansion memory, when the extended address register is updated with a value of 0x01 with the help of the command 17h, it will open Bank1 of the memory. The consequent 24-bit address

commands will lead to Bank1. The extended address register needs to be update with the respective value for access to other banks. This effectively converts the legacy 24-bit address command into 32-bit address commands.

30.6 Initialization/Application Information

This section provides the initialization and application information of the QuadSPI module.

30.6.1 Power Up and Reset

Note that the serial flash devices connected to the QuadSPI module may require special voltage characteristics of their inputs during power up or reset. It is the responsibility of the application to ensure this.

30.6.2 Available Status/Flag Information

This paragraph gives an overview of the different status and flag information available and their interdependencies for different use cases. Related registers are QSPI_SR and QSPI_FR. Refer to the related descriptions how to set up the QuadSPI module appropriately.

30.6.2.1 IP Commands

Refer to IP Configuration Register (QuadSPI_IPCR) for additional details not explicitly covered in this paragraph.

- **IP Commands - Normal Operation**

  Writing the QSPI_IPCR[SEQID] field triggers the execution of a new IP Command. Given that this is a legal command the QSPI_SR[IPACC] and the QSPI_SR[BUSY] bits are asserted simultaneously, immediately after the execution is started.

  When the instruction on the serial flash device has been finished these bits are de-asserted and the QSPI_FR[TFF] flag is set.

- **IP Commands - Error Situations**

  Refer to Table 30-436 below.

30.6.2.2 AHB Commands

Refer to Section 1, Reading Serial Flash Data into the QuadSPI Module, in Flash Read for additional details not explicitly covered in this paragraph.

- **AHB Commands - Normal Operation**

  Memory mapped read access to a serial flash address not contained in the AHB Buffer, triggers the execution of an AHB Command. Given that this is a legal command the QSPI_SR[AHBACC] and the QSPI_SR[BUSY] bits are asserted simultaneously immediately after the execution is started. When the instruction on the serial flash device has been finished these bits are de-asserted.

- **IP Commands - Error Situations**

  Refer to Table 30-436 below.

30.6.2.3 Overview of Error Flags

The following table gives an overview of the different error flags in the QSPI_FR register and additional error-related details.

Table 30-436. Overview of QSPI_FR Error Flags

Error Category	Error Flag in QSPI_FR	Command Execution on Serial Flash Device TFF Behavior (in case of IP commands only)	Description
AHB Error Flags	ABSEF	Flash transaction is aborted	AHB sequence contains • WRITE instruction • WRITE_DDR instruction
	ABOF	Flash transaction continues until it finishes	Set when the module tried to push data into the AHB buffer that exceeded the size of the AHB buffer. Only occurs due to wrong programming of the QSPI_BUFxCR[ADATSZ].
Miscellaneous Error Flags	DLPFF	Flash transaction continues until it finishes	Set when DATA_LEARN instruction was encountered in a sequence but no sampling point was found for the data learning pattern.
	ILLINE	Flash transaction aborted	Illegal instruction Error Flag – Set when an illegal instruction is encountered by the controller in any of the sequences.

Table continues on the next page...

Table 30-436. Overview of QSPI_FR Error Flags (continued)

Error Category	Error Flag in QSPI_FR	Command Execution on Serial Flash Device TFF Behavior (in case of IP commands only)	Description
Command Arbitration Errors	IPIEF	TFF not asserted in conjunction with that command	IP Command Error - caused when IP access is currently in progress (IP_ACC set) and • write attempt to QSPI_IPCR register. • write attempt to QSPI_SFAR register. • write attempt to QSPI_RBCT register.
	IPAEF		• AHB Command already running, another IP Command could not be executed. • AHB Command already running, write attempt to QSPI_IPCR[SEQID] field.
	IPGEF		• Exclusive access to the serial flash granted for AHB Commands, write attempt to QSPI_IPCR[SEQID] field.
IP Command Error	IUEF		• IP Command Usage Error
Buffer Related Errors	RBOF	TFF is asserted on completion	• RX Buffer Overrun
	TBUF		• TX Buffer Underrun

Note that only the buffer related errors are related to a transaction on the external serial flash. All the other errors do not trigger an actual transaction.

30.6.2.4 IP Bus and AHB Access Command Collisions

There are two flags related to this topic, the QSPI_FR[IPAEF] and QSPI_FR[IPIEF]. Refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of Flash Read section, for a description of the flags and Command Arbitration , for details about possible command collisions.

30.6.3 Exclusive Access to Serial Flash for AHB Commands

It is possible that several masters need to access the serial flash device connected to the QuadSPI module separately, one master by triggering IP Commands and reading the RX Buffer (via RBDx register) and the other masters by triggering AHB Commands (via ARDBx Registers). These two set of buffer (RBDR and ARDB Buffer) points to the same physical buffer.Refer to Figure 30-417 To avoid command collisions resulting in excessive latencies the QuadSPI module implements a request-handshake mechanism between the master triggering AHB Commands and the QuadSPI module allowing this specific master to request exclusive access to the serial flash device for AHB Commands. If this exclusive access is granted the execution of IP Commands is blocked. This resolves command collisions and excessive times where the AHB interface may be blocked.

If this capability is used in the device there is additional status and flag information available related to this mechanism. The QSPI_SR[AHBGNT] bit reflects the module-internal state that the exclusive access mentioned above is granted, any attempt to trigger an IP Command is rejected and results in the assertion of the QSPI_FR[IPGEF] flag. Refer to the descriptions of the related bit and flag for details.

It is within the responsibility of the application to set up the master using this mechanism appropriately, if used incorrectly no IP Commands at all can be triggered.

Two different cases can be distinguished:

30.6.3.1 RX Buffer Read via QSPI_ARDB Registers

In this case all masters share the AHB bus for RX Buffer as well as for AHB Buffer read. In this case the access to the AHB interface by the master triggering AHB Commands must be deferred until any pending IP Command has been finished **and** the RX Buffer readout has been finished as well. The QSPI ARDB Buffers access the Rx buffer i.e the data from the Rx Buffer is returned and no data from AHB Buffer is touched. This is the conservative use case, corresponding to the reset value 0 of the QSPI_RBCT[RXBRD] bit.

In this case the QSPI_SR[AHBGNT] bit is asserted not earlier than any running IP Command has been finished (QSPI_SR[IP_ACC] is 0), the RX Buffer has been read out completely (QSPI_RBSR[RDBFL] equal to 0) or no DMA read is pending (QSPI_SR[RXDMA] equal to 0 and Rx Buffer readout is via AHB(QSPI_RBCT[RXBRD]) equal to 1.

30.6.3.2 RX Buffer Read via QSPI_RBDR Registers

This is the preferred use case as an access to the AHB buffer (memory mapped flash) does not interfere with any IPS access to read the RBDR buffer. It is not possible that a pending AHB bus access triggered by an AHB Command stalls the AHB bus and blocks the RX Buffer readout since the RX Buffer is read via the IP bus based registers QSPI_RBDR0 to QSPI_RBDR31.

For this case it is recommended to program the QSPI_RBCT[RXBRD] bit to 1. The QSPI_SR[AHBGNT] bit is asserted immediately after any running IP Command has been finished (QSPI_SR[IP_ACC] is 0), the RX Buffer has been read out completely (QSPI_RBSR[RDBFL] equal to 0) or no DMA read is pending (QSPI_SR[RXDMA] equal to 0, allowing the master triggering AHB Commands to trigger AHB Commands as soon as possible without the need to wait for the RX Buffer readout to be finished.

30.6.4 Command Arbitration

In case of overlapping commands, the arbitration scheme is described in the following paragraphs under the assumption that the priority mechanism described in Exclusive Access to Serial Flash for AHB Commands is **not** used:

- During the execution of an IP Command, the running IP Command can't be terminated by issuing another IP Command or AHB Command. The QSPI_FR[IPIEF] flag is asserted when the host tries to write into the QSPI_IPCR register. When the host triggers an AHB Command (refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of Flash Read section, for details), this command is stalled until the currently running IP Command is finished.
- During the execution of an AHB Command, the running AHB Command can't be terminated by issuing an IP Command. The command is ignored and the QSPI_FR[IPAEF] flag is asserted. Refer to Flag Register (QuadSPI_FR) for the description of these flags.

  When another AHB Command is triggered the address of the memory mapped access is considered. If the requested address is currently read from the serial flash device, the running command is continued. If this is not the case the currently running command is terminated and another AHB Command related to the requested address is executed. Refer to sub-section "Reading Serial Flash Data into the QuadSPI Module" of Flash Read section, for further details.

In case of coinciding commands the IP Command is triggered and the AHB Command is stalled until the IP Command has been finished (QSPI_SR[IP_ACC] has been deasserted).

The IP Commands ignored in case of command collision will not result in the assertion of the QSPI_FR[TFF] flag.

30.6.5 Flash Device Selection

Regardless of the SFM Command (IP or AHB) the access mode is selected by specifying the 32 bit address value for the following SFM Command.

For IP Commands the access mode is selected with the address programmed into the QSPI_SFAR register. Refer to Serial Flash Address Register (QuadSPI_SFAR) for details.

For AHB Commands the access mode is determined by the memory mapped address which is accessed Refer to AMBA Bus Register Memory Map for details.

30.6.6 DMA Usage

For the complete description of the DMA module refer to the related DMA Controller chapter. In this paragraph only the details specific to the DMA usage related to the QuadSPI module are given.

30.6.6.1 DMA Usage in Normal Mode

30.6.6.1.1 Bandwidth considerations

Careful consideration of the throughput rate of the entire chain (serial flash -> AHB bus / IP Bus -> DMA controller) involved in the read data process is essential for proper operation. Such analysis must take into account not only the data rate provided by the serial flash but also the data rate of the AHB bus and the performance of the DMA controller in reading data from the RX buffer.

Two figures must match for proper operation, that means that the data rate provided by the serial flash device must not exceed the average RX Buffer readout data rate. Otherwise, the longer this state persists, a RX Buffer overflow will result.

AHB Bus Side:

The total number of bus cycles for each DMA Minor Loop completion is added from the following components:

- Overhead for each minor loop, given by DMA controller: Assume 10 cycles

- Overhead due to clock domain crossing: Assume 2 cycles
- Number of bus clock cycles required for 8 bytes (64 bit read size): Assume 2 cycles (read/write sequence of DMA controller)

Note that the size of the minor loop is determined by the size of the QSPI_RBCT[WMRK] field, therefore the overhead given above distributes among (QSPI_RBCT[WMRK]+1)/2 read accesses of 64 bit each.

The following table gives some examples for typical use cases:

Table 30-437. Access Duration Examples - Bus Clock Side

QSPI_RBCT[WMRK]	Number of Bytes per DMA Loop [1]	Number of Bus Clock cycles for DMA Minor Loop	Time Duration of DMA Minor Loop for 120Mhz Bus clock Frequency
0	4	12+2 = 14	~117ns
1	8	12+2 = 14	~117ns
3	16	12+4 = 16	~133ns
7	32	12+8 = 20	~167ns
11	48	12+12 = 24	~200ns

1. DMA Loop means one Minor Loop Completion which is equivalent to one.

Serial Flash Device Side:

The number of serial flash cycles can be determined in the following way:

- Number of serial flash clock cycles required to read 4 bytes, corresponding to one RX Buffer entry(setup of command and address not considered): 2 cycles for Quad DDR mode instructions in Parallel Flash Mode, 4 cycles for Quad(SDR) mode instruction in parallel flash mode or Dual IO DDR mode instruction in parallel flash mode, 8 cycles for Quad Mode (SDR) instructions in Individual Flash Mode etc.
- Overhead due to clock domain crossing : 1 cycle.

The following table lists the number of clock cycles required to read the data from the serial flash corresponding to the different settings of the QSPI_RBCT[WMRK] field:

Table 30-438. Access Duration Examples - Serial Flash side

QSPI_RBCT[WMRK] setting	Num Bytes per DMA Loop [1]	Num SCKFx for 60MHz SCKFx			Time duration of Flash data readout for 60MHz SCKFx (~16.6ns period)		
		IFM [2] Quad	IFM Quad DDR	[3] PFM Quad DDR	IFM Quad	IFM Quad DDR	PFM Quad DDR
0	4	9	5	3	~150ns	~83ns	~50ns
1	8	17	9	5	~282ns	~150ns	~83ns
3	16	33	17	9	~548ns	~282ns	~150ns
7	32	65	33	17	~1079ns	~548ns	~282ns
11	48	97	49	25	~1610ns	~813ns	~415ns

1. DMA Loop means one Minor loop completion which is equivalent to one Major Loop iteration.
2. Individual flash mode.
3. Parallel flash mode.

From the examples given in the two tables above, it can be seen that depending on the relationship between the Bus clock and Serial flash clock frequencies, there are settings possible where the serial flash provides the read data faster than the AHB bus can read out the RX buffer. In the above tables, it is the case of PFM Quad DDR mode with Watermark up to 3 and other cases. In these cases, the RX buffer data keeps accumulating over time and will eventually overflow. To avoid RX Buffer overflow, the data transaction size should be small enough.

A complementary example would be when the watermark is set to be too high. In such a case, the time taken by the DMA to read out the RX buffer entries should be smaller than the time taken by the controller to push in the remaining entries in the buffer.

30.6.7 Parallel mode

QuadSPI can access two flashes in parallel. This increases the throughput of the QuadSPI by two times. Only read operations and x1 mode write are allowed in parallel mode. In case a write transaction is initiated in with mode than one pad in parallel mode, QSPI_FR[IUEF] is set. When dual die flashes are accessed in parallel mode, it is mandatory for flash A1 to be of the same size as B1 and A2 to be of the same size as B2. The following figure shows how QuadSPI maps the incoming addresses to the different flashes connected on board.

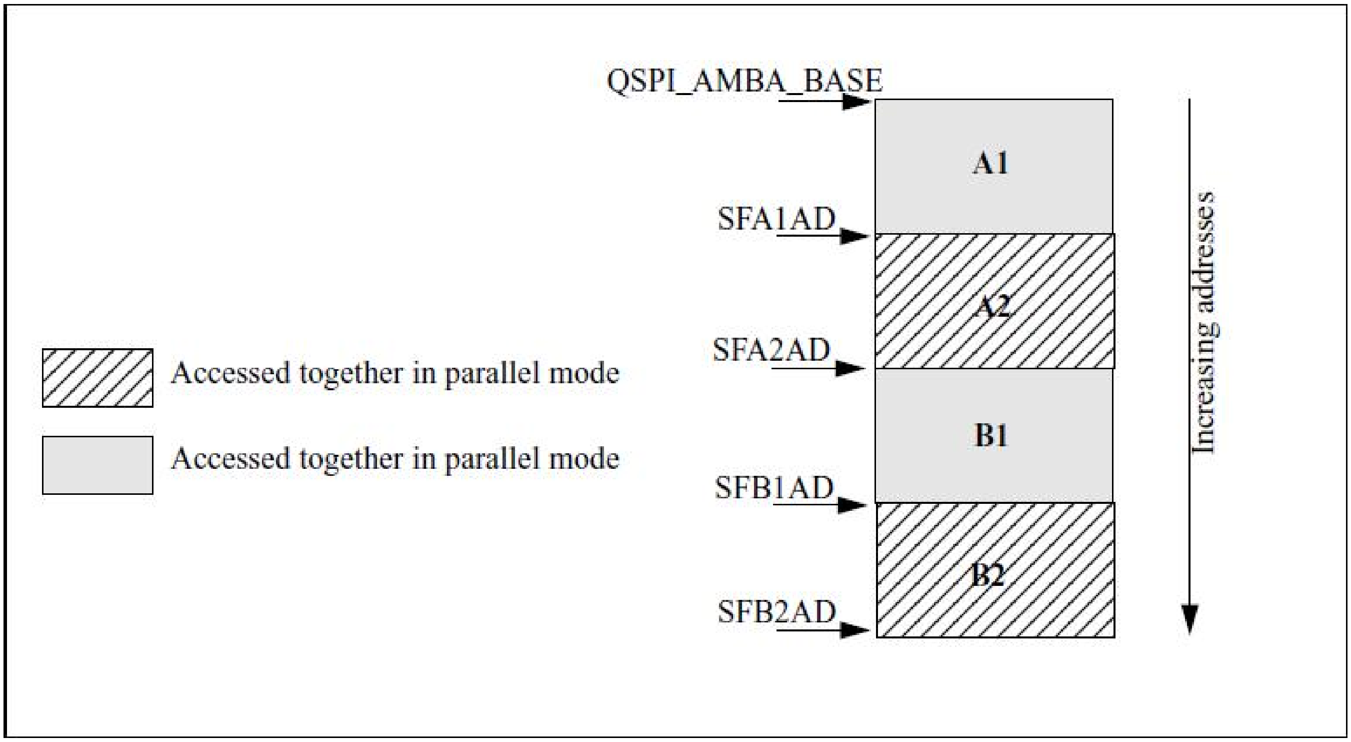

Figure 30-418. Flash addressing

An example programming for parallel mode access is given below (flash sizes are assumed to be 256MB):

- QSPI_AMBA_BASE - 0x10000000
- QSPI_SFA1AD[TPADA1] - 0x20000000
- QSPI_SFA2AD[TPADA2] - 0x30000000
- QSPI_SFB1AD[TPADB1] - 0x40000000
- QSPI_SFB2AD[TPADB2] - 0x50000000

In order to access the first location of A1/B1 pair, the incoming address should be 0x10000000. QSPI_AMBA_BASE is subtracted from this address and the result is divided by two. Therefore, address provided to flash A1 and B1

Flash Address = (Memory mapped address - QSPI_AMBA_BASE)/2

For Memory Mapped address:

- 0x10000000, flash address: 0x0 (Or, the first address of flash A1 and B1)
- 0x10000004, flash address: 0x2
- 0x10000008, flash address: 0x4 etc.

Similarly, in order to access the first location of A2/B2 pair, the incoming address should be 0x30000000.

Flash Address = (Memory mapped address - SFA2AD)/2

For Memory Mapped address:

- 0x30000000, flash address: 0x0 (Or, the first address of flash A2 and B2)
- 0x30000004, flash address: 0x2
- 0x30000008, flash address: 0x4 etc.

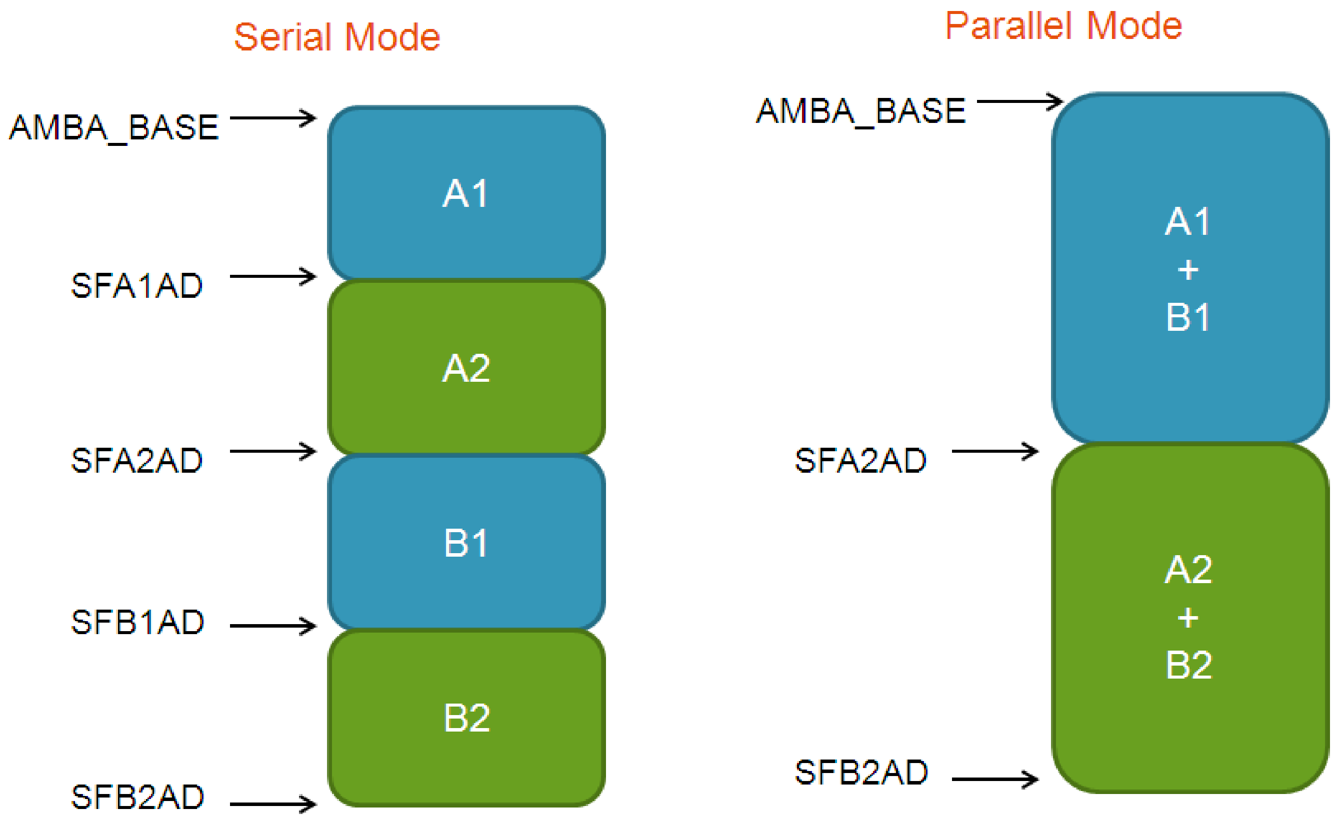

Figure 30-419. Memory map - Serial and Parallel

30.7 Byte Ordering - Endianess

QuadSPI provides support for swapping the flash read/write data based on the configuration of the QSPI_MCR[END_CFG]. By default the data is always returned in 64bit BE format on the AHB bus and 32bit BE format on the IPS interface when read via the RX buffer and written in 32bit BE format when written via the TX buffer.

The table(QSPI_MCR[END_CFG]) below shows the complete bit ordering. BE signifies Big Endian which means the high order bits of the associated data vectors are associated with low order address positions. LE signifies Little Endian which means the lower order bits of the associated data vectors are associated with low order address positions.Refer to figure Figure 30-417

Table 30-439. QSPI_MCR[END_CFG]

00	64 bit BE
01	32 bit LE
10	32 bit BE
11	64 bit LE

The tables below (Byte ordering configuration in AHB) and (Byte ordering configuration in IPS) show how this configuration is implemented in QSPI AHB and IPS interfaces respectively. B in the table signifies Byte and the index 1-8 refers to the byte position i.e. 1 refer to bits[7:0], 8 refer to bits[63:56] and so on.

Table 30-440. Byte ordering configuration in AHB

64 bit BE	B1	B2	B3	B4	B5	B6	B7	B8
64 bit LE	B8	B7	B6	B5	B4	B3	B2	B1
32 bit BE	B5	B6	B7	B8	B1	B2	B3	B4
32 bit LE	B4	B3	B2	B1	B8	B7	B6	B5

Table 30-441. Byte ordering configuration in IPS

32BE	B1	B2	B3	B4
32LE	B4	B3	B2	B1

The examples below show the byte ordering in 64 bit BE configuration for AHB Buffer and 32 bit BE for TX/RX Buffer:

30.7.1 Programming Flash Data

CPU write instructions to the QSPI_TBDR register like

- Write QSPI_TBDR -> 0x01_02_03_04
- Write QSPI_TBDR -> 0x05_06_07_08

result in the following content of the TX Buffer:

Table 30-442. Example of QuadSPI TX Buffer

TX Buffer Entry	Content
0	32'h01_02_03_04
1	32'h05_06_07_08

Programming the TX Buffer into the external serial flash device results in the following byte order to be sent to the serial flash:

- 01…02…03…04…05…06…07…08

30.7.2 Reading Flash Data into the RX Buffer

Reading the content from the same address provides the following sequence of bytes, identical to the write case:

- 01…02…03…04…05…06…07…08

This results in the RX Buffer filled with:

Table 30-443. Resulting RX Buffer Content

RX Buffer Entry	Content
0	32'h01_02_03_04
1	32'h05_06_07_08

30.7.2.1 Readout of the RX Buffer via QSPI_RBDRn

The RX Buffer content appears at CPU read access via the IP SkyBlue interface in the following order:

- Read QSPI_RBDR0 <- 0x01_02_03_04
- Read QSPI_RBDR1 <- 0x05_06_07_08

30.7.2.2 Readout of the RX Buffer via ARDBn

The RX Buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- (1a): 32 Bit Access: Read QSPI_ARDB0 <- 0x01_02_03_04
- (2a): 32 Bit Access: Read QSPI_ARDB1 <- 0x05_06_07_08
- (1b/2b): 64 Bit Access: Read QSPI_ARDB0 <- 0x01_02_03_04_05_06_07_08

30.7.3 Reading Flash Data into the AHB Buffer

Reading the content from the same address as it was written to provides the following sequence of bytes, identical to the write case:

- 01…02…03…04…05…06…07…08

This results in the AHB Buffer filled with:

Table 30-444. Resulting AHB Buffer Content

AHB Buffer Entry	Content
0	64'h01_02_03_04_05_06_07_08

30.7.3.1 Readout of the AHB Buffer via Memory Mapped Read

The AHB Buffer content appears at read access on the AMBA AHB interface at the QuadSPI module boundary:

- (1a): 32 Bit Read Access: <- 0x01_02_03_04
- (2a): 32 Bit Read Access: <- 0x05_06_07_08
- (1/2): 64 Bit Read Access: <- 0x01_02_03_04_05_06_07_08

30.8 Serial Flash Devices

Several different vendors make flash devices with a QuadSPI interface. At present there is no set standard for the QuadSPI instruction set. Most common commands currently have the same instruction code for all vendors, however some commands are unique to specific vendors. Some example sequences are provided below.

30.8.1 Example Sequences

This section provides the example sequences of the QuadSPI module.

Table 30-445. Exit 4 x I/O Read Enhance Performance Mode (XIP) (Macronix) and Read Status

INSTR	PAD	OPERAND	COMMENT
CMD	0x0	0xEB	4xIO Read Command
ADDR	0x2	0x18	24 Bit address to be send on 4 pads
MODE	0x2	0x00	2 mode cycles (exit XIP)
DUMMY	0x0	0x04	4 dummy cycles
READ	0x2	0x08	Read 64 bits
CMD	0x0	0x05	Read Status register
READ	0x0	0x01	Status register data
STOP	0x0	0x00	STOP, Instruction over

30.8.1.1 Fast Read Sequence (Macronix/Numonyx/Spansion/Winbond)

The following table shows the fast read sequence for Macronix/Numonyx/Spansion/Winbond flashes.

Table 30-446. Fast Read sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x0B	Fast Read command = 0x0B
ADDR	0x0	0x18	24 Addr bits to be sent on one pad
DUMMY	0x0	0x08	8 Dummy cycles
READ	0x0	0x04	Read 32 Bits on one pad
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

30.8.1.2 Fast Dual I/O DT Read Sequence (Macronix)

The following table shows the Fast Dual I/O DT read sequence for Macronix flashes.

Table 30-447. Fast Dual I/O DT Read sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xBD	Fast Dual I/O DT read command = 0xBD

Table continues on the next page...

Table 30-447. Fast Dual I/O DT Read sequence (continued)

Instruction	Pad	Operand	Comment
ADDR_DDR	0x1	0x18	24 Addr bits to be sent on 2 pads in DDR mode
MODE4_DDR	0x1	0x00	P2=P0 or P3=P1 is necessary. Refer to Macronix datasheet for details. One clock cycle for mode.
DUMMY	0x0	0x06	6 Dummy cycles
READ_DDR	0x1	0x04	Read 32 Bits on 2 pads in DDR mode
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

30.8.1.3 Fast Read Quad Output (Winbond)

The following table shows the Fast read quad output sequence for Winbond memories

Table 30-448. Fast Read Quad output sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x6B	Fast read quad output command = 0x6B
ADDR	0x0	0x18	24 Addr bits to be sent on 1 pad
DUMMY	0x0	0x08	8 Dummy cycles
READ	0x2	0x04	Read 32 Bits on 4 pads
JMP_ON_CS	0x0	0x00	Jump to instruction 0 (CMD)

30.8.1.4 4 x I/O Read Enhance Performance Mode (XIP) (Macronix)

The following table shows the 4 x I/O Read Enhance Performance Mode for Macronix flashes. The enhanced performance mode is also known as XIP mode.

Table 30-449. Fast Read Quad output sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xEB	4xI/O Read command = 0xEB
ADDR	0x2	0x18	24 Addr bits to be sent on 4 pads
MODE	0x2	0xA5	2 mode cycles
DUMMY	0x0	0x04	4 Dummy cycles
READ	0x2	0x04	Read 32 Bits on 4 pads
JMP_ON_CS	0x0	0x01	Jump to instruction 1 (ADDR)

When in XIP mode the software should ensure that all the flashes connected to the controller are in XIP mode. As a part of initializing the controller, all the flashes may be enabled with XIP by carrying out dummy reads.

30.8.1.5 Dual Command Page Program (Numonyx)

The following table shows the Dual command page program sequence for Numonyx flashes.

Table 30-450. Dual Command Page Program sequence

Instruction	Pad	Operand	Comment
CMD	0x1	0x02	Dual command page program = 0x02 on 2 pads
ADDR	0x1	0x18	24 Addr bits to be sent on 2 pads
WRITE	0x1	0x20	Write 32 Bytes on 2 pads
STOP	0x0	0x00	STOP, Instruction over

30.8.1.6 Sector Erase (Macronix/Spansion/Numonyx)

The following table shows the Sector erase sequence for Macronix/Spansion/Numonyx flashes

Table 30-451. Sector Erase sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0xD8	Sector erase command = 0xD8
ADDR	0x0	0x18	24 Addr bits to be sent on 1 pad
STOP	0x0	0x00	STOP, Instruction over

30.8.1.7 Read Status Register (Macronix/Spansion/Numonyx/Winbond)

The following table shows the Read status register sequence for Macronix/Spansion/Numonyx/Winbond flashes.

Table 30-452. Read Status Register Sequence

Instruction	Pad	Operand	Comment
CMD	0x0	0x05	Read status register command = 0x05
READ	0x0	0x01	Read status register data
STOP	0x0	0x00	STOP, Instruction over

30.8.2 Dual Die Flashes

Certain serial flash vendors provide dual-die packages which are essentially two devices (dies) stacked within the same package to increase the memory capacity of a single package. These two devices within a package share the same data and clock pins, but have individual Chip Selects. QuadSPI controller provides support for two dual-die packages to be connected simultaneously. The figure below shows the two dual-die packages and the naming conventions used in this document. For simplicity, the data pins are shown to be unidirectional.

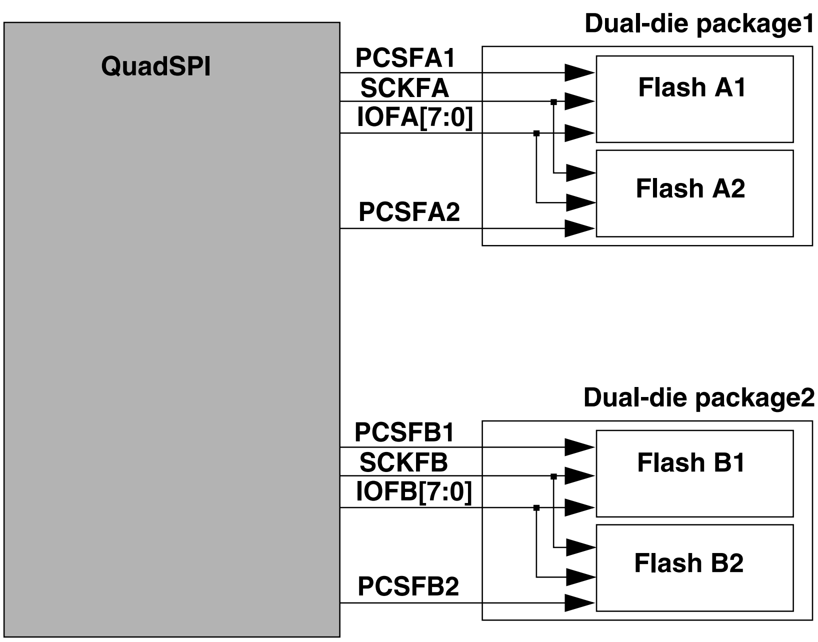

Figure 30-420. Dual-die support

Since the two devices within one package share the same i/o pads, they cannot function in parallel mode. Software should ensure that when QuadSPI is configured in parallel mode the two selected flash devices are from different dual-die packages.

30.8.3 Boot initialization sequence

The following are the recommended sequence of steps for booting from QuadSPI (please refer to #converted-map for details).

- System out of reset and flash available (300us)

- Clocks still at very low frequency. Clock tree configured, I/O pins configured. First request sent to QuadSPI for address 0x0 of flash.
- The reset command sequence in QuadSPI has 0x03 (basic read command) which is applicable to all flashes at < 50MHz serial flash clock
- The first few bytes of data is read from the flash which contains the following information:
  - The total sizes of all the flashes connected on board
  - Whether DDR mode supported
  - Frequency of DDR operation
  - Continuous mode entry sequence
  - 24bit or 32bit addressing (assuming 24bit for first accesses)
- All the serial flashes are configured
  - Quad Mode enabled
  - Dummy reads to enter into XIP
- QuadSPI is configured
  - Parallel enable set
  - LUT configured for highest performance reads
  - DDR mode enabled (if applicable)
  - Buffers configured
- Serial flash clock frequency increased.
- Boot reads happen in parallel, DDR enabled, quad output mode @66MHz.

30.8.4 Serial Flash Clock Frequency Limitations

Certain commands of some serial flash devices are limited in the frequency applied to the serial flash device on command execution. In order to support these commands without having to relibrate the module clocks, the the serial flash device clock can be divided by 2 (half speed) by setting the QSPI_SMPR[HSENA] bit. The SCLK will return to full speed once the the QSPI_SMPR[HSENA] bit is cleared.

30.9 Internal Sampling of Serial Flash Input Data

30.9.1 Internal Sampling of Serial Flash Input Data

Depending from the actual implementation there is a delay between the internal clocking in the QuadSPI module and the external serial flash device.Refer to the following figure for an overview of this scheme.

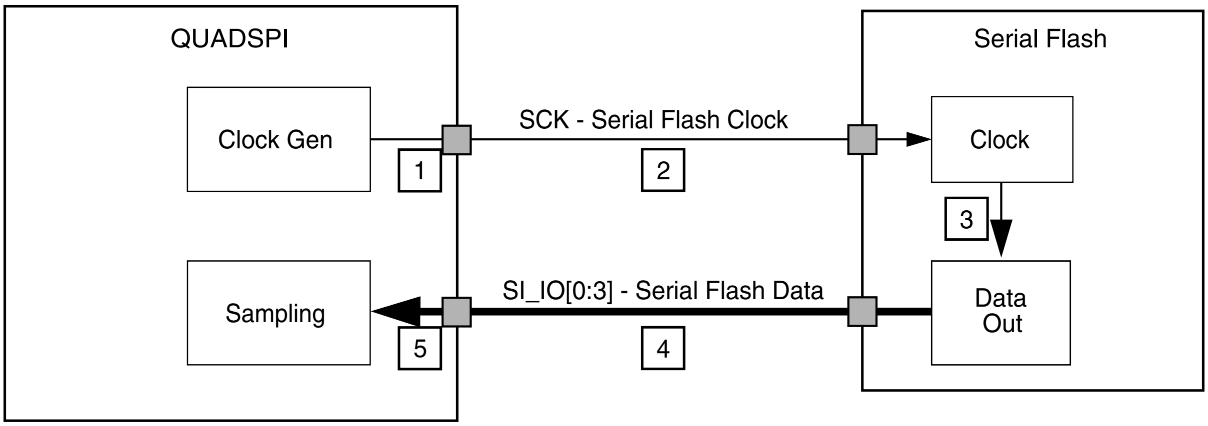

Figure 30-421. Serial Flash Sampling Clock Overview

Note

The arrival of the serial flash data in the sampling stage of the QuadSPI module are given in the following figure. Note that the amount of the total delay $t_{Del,total}$ is very specific to the characteristics of the actual implementation.

Note also that the serial flash device clock SCK is inverted with respect to the QuadSPI internal reference clock.

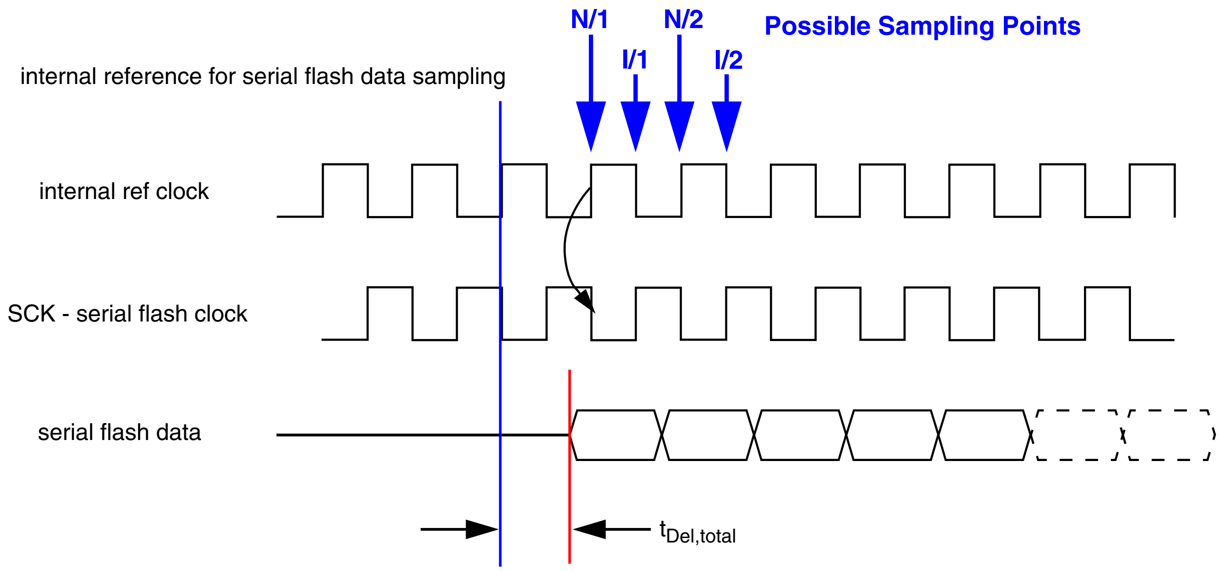

Figure 30-422. Serial Flash Sampling Clock Timing

The rising edge of the internal reference clock is taken as timing reference for the data output of the serial flash. After a time of $t_{Del,total}$ the data arrive at the internal sampling stage of the QuadSPI module.

According to the Serial Flash Sampling Clock Overview figure, the following parts of the delay chain contribute to $t_{Del,total}$:

1. Output delay of the serial flash clock output of the device containing the QuadSPI module
2. Wire delay of application/PCB from the device containing the QuadSPI module to the external serial flash device
3. Clock to data out delay of the external serial flash device, including input and output delays
4. Wire delay of application/PCB from the external serial flash device to the device containing the QuadSPI module
5. Input delay belonging to the data in input

The possible points in time for the sampling of the incoming data are denoted as N/1, I/1, N/2 and I/2 above. The sampling point relevant for the internal sampling is configured in the QSPI_SMPR register, refer to Sampling Register (QuadSPI_SMPR) for details. Note that the falling edges of the reference clock are not actually used, instead the inverted clock is used for sampling at these positions. The following table gives an overview of the available configurations for the commands running at regular (full) speed:

Table 30-453. Sampling Configuration

Sampling Point	Description	Delay [FSDLY] [HSDLY]	Phase [FSPHS] [HSPHS]	QSPI_SMPR for Full Speed Setting[1]
N/1	sampling with non-inverted clock, 1 sample delay	0	0	0x0000000x
I/1	sampling with inverted clock, 1 sample delay	0	1	0x0000002x
N/2	sampling with non-inverted clock, 2 samples delay	1	0	0x0000004x
I/2	sampling with inverted clock, 2 samples delay	1	1	0x0000006x

1. 'x' is not considered here

Depending from the actual delay and the serial flash clock frequency the appropriate sampling point can be chosen. The following remarks should be considered when selecting the appropriate setting:

- Theoretically there should be 2 settings possible to capture the correct data since the serial flash output is valid for 1 clock cycle, disregarding rise and fall times and timing uncertainties.
- Depending from the timing uncertainties it may turn out in actual applications that only one possible sample positions remains. This is subject to careful consideration depending from the actual implementation.
- The delay $t_{Del,total}$ is an absolute size to shift the point in time when the serial flash date get valid at the QuadSPI input.
- For decreasing frequency of the serial flash clock the distance between the edges increases. So for large differences in the frequency the required setting may change.
- For commands running at half of the regular serial flash clock (QSPI_SMPR[HSENA] bit set) the sampling point must be figured separately to allow for the compensation of the absolute shift in time with respect to the sample-relative setting in the QSPI_SPMPR register.

30.9.2 DDR Mode

When the serial flashes function in DDR mode, the data is valid for only half a clock cycle. This, along with the fact that the time for which the data is actually valid is smaller than half a clock cycle, requires that we provide closely spaced sampling points. The QuadSPI samples the incoming data at multiple sampling points provided by a 4x serial

flash clock in DDR mode. The figure below shows the different sampling points as configured by QSPI_SMPR[DDRSMP].The FSDLY/FSPHS and HSDLY/HSPHS bits are ignored for DDR instructions.

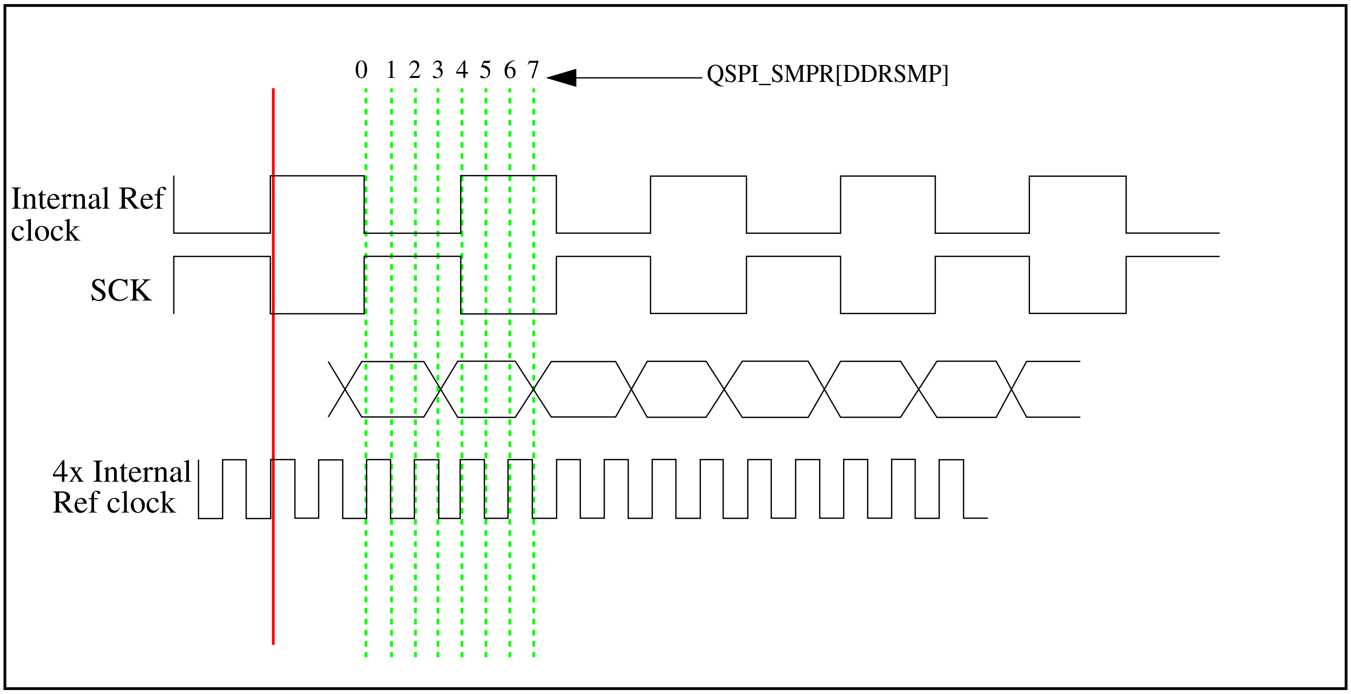

Figure 30-423. DDR sampling edges

Software should ensure that the correct sampling value is configured in the QSPI_SMPR[DDRSMP] register.

30.10 Data Strobe Signal functionality

Some external serial flashes provide the data strobe (DQS/RDS) output which is fed directly to the QuadSPI module. The strobe (DQS/RDS) signal needs to be delayed to have the edges aligned to the data valid period. QuadSPI internally samples the incoming data at posedge of the strobe signal for SDR and on both the edges of the strobe signal for DDR. Refer to the figure for more detail.

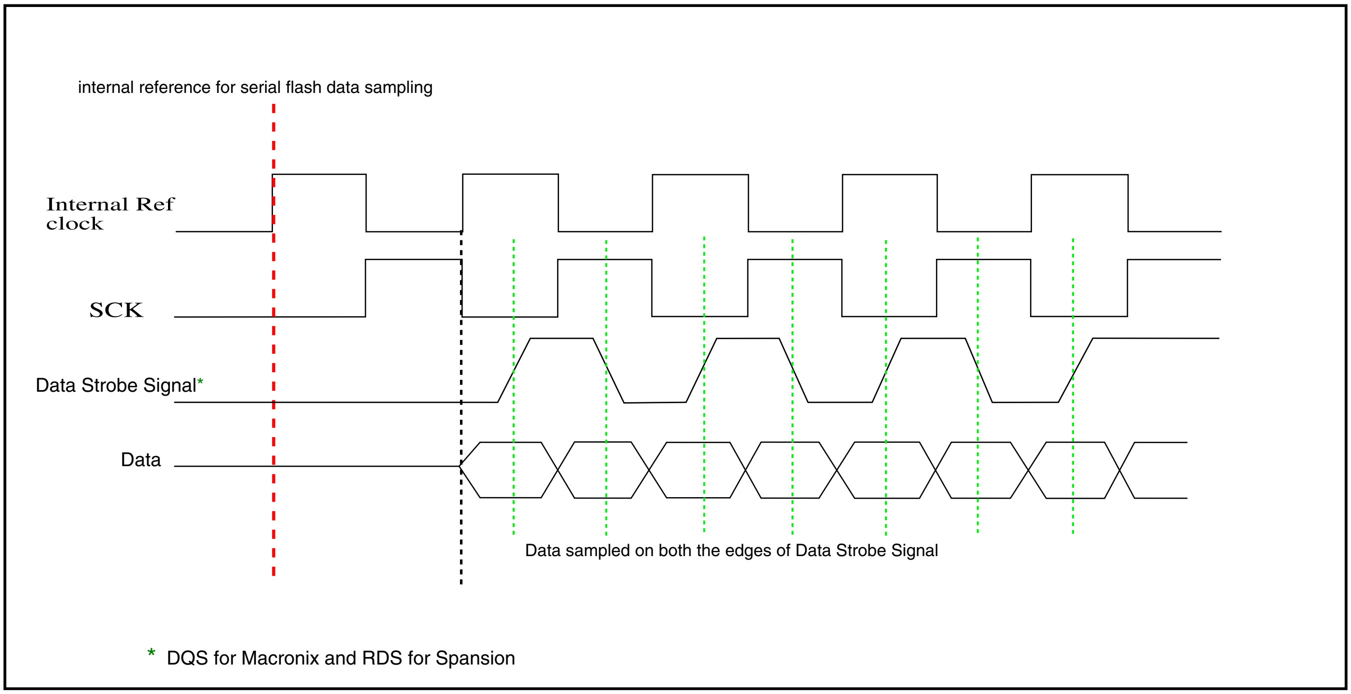

Figure 30-424. Data strobe signal functionality

Chapter 31
NAND Flash Controller (NFC)

31.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The NAND flash controller (NFC) interfaces to standard NAND flash memory devices. It is composed of various control logic units and a 9 KB SRAM buffer. The NFC provides a glueless interface to 8- and 16-bit NAND flash devices with page sizes of 512 bytes, 2 KB, 4 KB, 8 KB and 16 KB.

Throughout this chapter the following terms are used:

- Block — (specified by device) smallest erasable unit in a NAND device, consisting of multiple pages
- Page — (specified by device) unit of flash data containing main and spare areas
- Main area of a page — stores data
- Spare area of a page — stores ECC and other software information
- Sector — an elementary transfer unit
  - For devices with pages of 2KB and smaller, this is the same size of the page
  - For devices with pages larger than 2KB, the pages are split into multiple virtual pages. In this case, the sector size is the size of the virtual page
- Virtual page — is the physical page size divided by the splitting factor, NFC_CFG[PAGECNT]

- ECC — error-correcting code
- BCH (Bose Chaudhuri Hocquenghem) — cyclic error-correcting code that corrects multi-bit errors

31.1.1 Block Diagram

The following is a block diagram of the NAND flash controller.

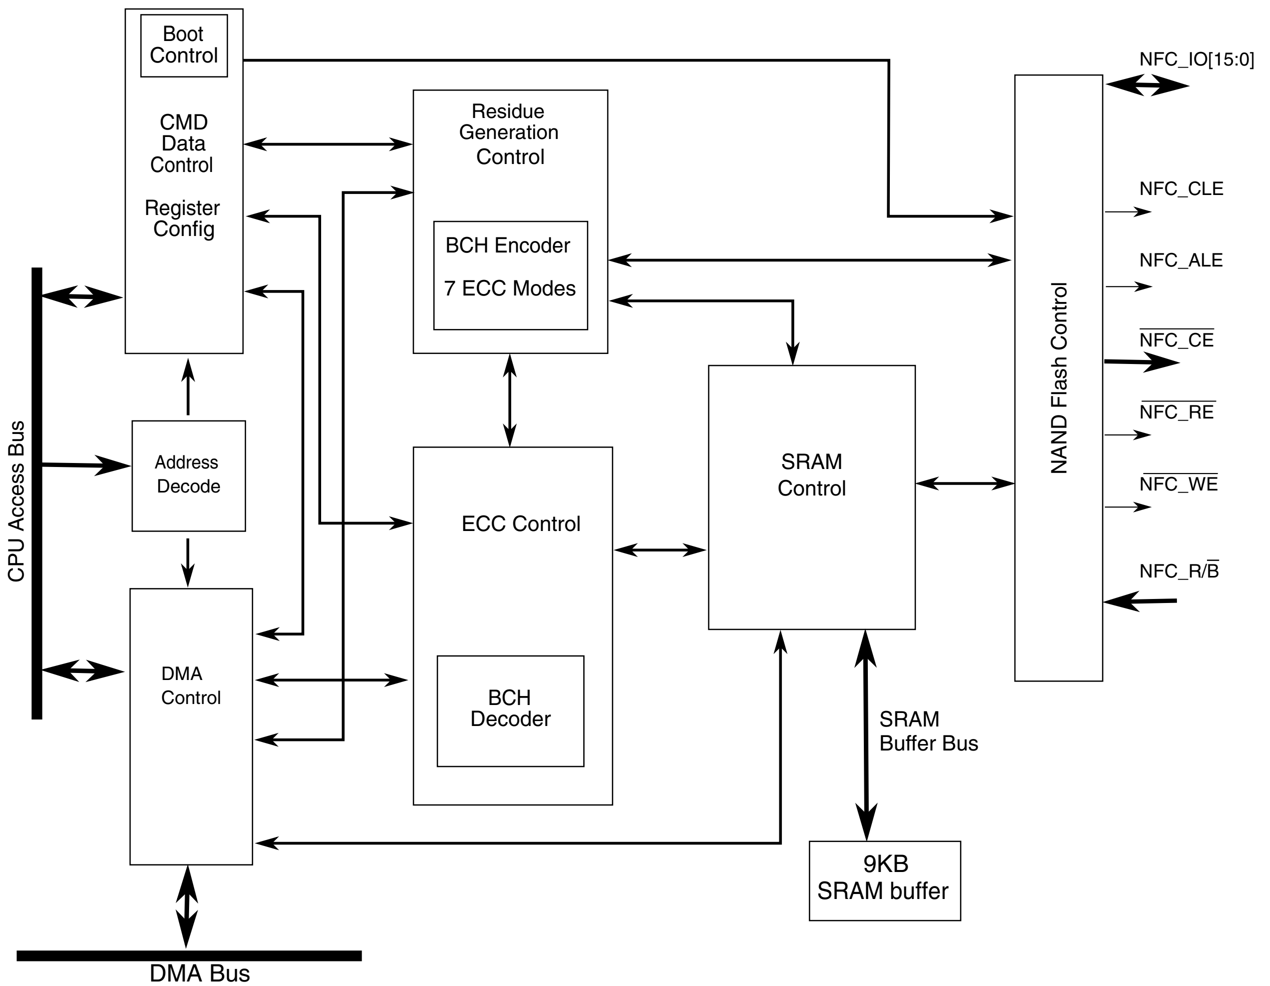

Figure 31-1. NAND Flash Controller Block Diagram

31.1.2 Features

The NAND flash controller includes the following features:

- 8- and 16-bit NAND flash interface

- 9 KB RAM buffer
    - Memory-mapped registers and SRAM buffer
- Supports all NAND flash products regardless of density/organization
- Supports flash device commands, such as page read, page program, reset, block erase, read status, read ID, copy-back, multiplane read/program, interleaved read/program, random input/output, read in EDO mode.
- Integrated DMA engine
    - Two configurable DMA channels
        - Use DMA channel 1 only to read/write a page for main and spare area of a page
        - Use DMA channel 1 to read/write the main area of a page, and DMA channel 2 for the spare area
- ECC mode
    - In ECC mode, NFC supports 4/6/8/12/16/24/32-bit error correction.
    - ECC mode can be bypassed.
- Boot from page size ≥ 2KB flash (x8) without extra control

31.2 External Signal Description

The signals shown in the next table are used to control NAND flash device.

Table 31-1. NFC Signal Properties

Name	Function	I/O	Reset
NFC_ALE	Flash address latch enable	O	1
$\overline{\text{NFC\_CE}}$	Flash chip enable	O	1
NFC_CLE	Flash command latch enable	O	1
NFC_R/$\overline{\text{B}}$	Flash ready/busy	I	Pull up[1]
$\overline{\text{NFC\_RE}}$	Flash read enable	O	1
$\overline{\text{NFC\_WE}}$	Flash write enable	O	1
NFC_IO[15:0]	Flash data bus	I/O	—

1. Need to configure both PE and PS bit to 1'b1 of pin control register PORTC_PCR18 to make NFC_R/B pull up, when PTC18 is configured to MUX=6 (NFC_R/B).

31.3 Memory Map/Register Definition

This section defines the NAND flash controller's registers.

NFC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
400E_3F00	Flash command 1 (NFC_CMD1)	32	R/W	30FF_0000h	31.3.1/1300
400E_3F04	Flash command 2 (NFC_CMD2)	32	R/W	007E_E000h	31.3.2/1301
400E_3F08	Column address (NFC_CAR)	32	R/W	0000_0000h	31.3.3/1302
400E_3F0C	Row address (NFC_RAR)	32	R/W	1100_0000h	31.3.4/1302
400E_3F10	Flash command repeat (NFC_RPT)	32	R/W	0000_0000h	31.3.5/1303
400E_3F14	Row address increment (NFC_RAI)	32	R/W	0000_0001h	31.3.6/1304
400E_3F18	Flash status 1 (NFC_SR1)	32	R	0000_0000h	31.3.7/1304
400E_3F1C	Flash status 2 (NFC_SR2)	32	R	0000_0000h	31.3.8/1305
400E_3F20	DMA channel 1 address (NFC_DMA_CH1)	32	R/W	0000_0000h	31.3.9/1305
400E_3F24	DMA configuration (NFC_DMACFG)	32	R/W	0000_0000h	31.3.10/ 1306
400E_3F28	Cach swap (NFC_SWAP)	32	R/W	0FFE_0FFEh	31.3.11/ 1306
400E_3F2C	Sector size (NFC_SECSZ)	32	R/W	0000_0420h	31.3.12/ 1307
400E_3F30	Flash configuration (NFC_CFG)	32	R/W	000E_A631h	31.3.13/ 1308
400E_3F34	DMA channel 2 address (NFC_DMA_CH2)	32	R/W	0000_0000h	31.3.14/ 1310
400E_3F38	Interrupt status (NFC_ISR)	32	R/W	6000_0000h	31.3.15/ 1311

31.3.1 Flash command 1 (NFC_CMD1)

Address: 400E_0000h base + 3F00h offset = 400E_3F00h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	BYTE2								BYTE3								0															
W																																
Reset	0	0	1	1	0	0	0	0	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

NFC_CMD1 field descriptions

Field	Description
31–24 BYTE2	Second command byte that may be sent to the flash device

Table continues on the next page...

NFC_CMD1 field descriptions (continued)

Field	Description
23–16 BYTE3	Third command byte that may be sent to the flash device
15–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

31.3.2 Flash command 2 (NFC_CMD2)

Address: 400E_0000h base + 3F04h offset = 400E_3F04h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	BYTE1								CODE

NFC_RAR field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28 RB0	Ready/busy 0 enable Determines if NFC_R/ $\overline{\text{B}}$ 0 is waited on a wait for R/ $\overline{\text{B}}$ command. If an equal number of $\overline{\text{NFC\_CE}}$ and NFC_R/ $\overline{\text{B}}$ lines are used, the CS *n* and RB *n* fields must contain identical values. If only one NFC_R/ $\overline{\text{B}}$ is used, then CS *n* determines the true chip select, and this field is always 1. 0 NFC_R/ $\overline{\text{B}}$ 0 is disabled 1 NFC_R/ $\overline{\text{B}}$ 0 is enabled
27–26 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
25 CS1	Chip select 1 enable 0 $\overline{\text{NFC\_CE1}}$ is disabled 1 $\overline{\text{NFC\_CE1}}$ is enabled
24 CS0	Chip select 0 enable 0 $\overline{\text{NFC\_CE0}}$ is disabled 1 $\overline{\text{NFC\_CE0}}$ is enabled
23–16 BYTE3	Third byte of row address
15–8 BYTE2	Second byte of row address
7–0 BYTE1	First byte of row address

31.3.5 Flash command repeat (NFC_RPT)

Address: 400E_0000h base + 3F10h offset = 400E_3F10h

Bit	31–16	15–0
R	0	COUNT
W		
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

NFC_RPT field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–0 COUNT	16-bit repeat count Determines how many times NFC_CMD2[CODE] is executed. If 0 or 1, the flash command is executed once.

31.3.6 Row address increment (NFC_RAI)

When auto-increment of row address is enabled (NFC_CFG[AIAD] = 1), the row address is incremented as follows:

```
new{NFC_RAR[BYTE3, BYTE2, BYTE1]} =
                            {NFC_RAR[BYTE3], NFC_RAR[BYTE2], NFC_RAR[BYTE1]} +
{NFC_RAI[INC3, INC2, INC1]}
```

Address: 400E_0000h base + 3F14h offset = 400E_3F14h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								INC3								INC2								INC1

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

NFC_DMACFG field descriptions

Field	Description
31–20 COUNT1	Number of bytes to be transferred by DMA channel 1. It should be multiple of 8 bytes.
19–13 COUNT2	Number of bytes to be transferred by DMA channel 2. It should be multiple of 8 bytes.
12–9 OFFSET2	256-byte offset for DMA channel 2. DMA channel 2 transfer starts at this offset count x 256 bytes. For example, if OFFSET2 = 0x2, DMA channel 2 transfer starts at 0x200.
8–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1 ACT1	DMA channel 1 status 0 Inactive 1 Active, and transfers to memory when triggered
0 ACT2	DMA channel 2 status 0 Inactive 1 Active, and transfers to memory when triggered

31.3.11 Cach swap (NFC_SWAP)

When DMA transfers data to/from the NFC cache (NFC SRAM buffer), or when the CPU reads or writes data to/from the NFC cache via the internal bus, all accesses that go to NFC_SWAP[ADDR1] are directed to NFC_SWAP[ADDR2]. Likewise, all accesses that go to NFC_SWAP[ADDR2] are directed to NFC_SWAP[ADDR1].

The feature allows the bad block marker in the first position of the spare area of a page. Because of the way the flash controller interleaves data and ECC bytes on flash devices with page sizes larger than 2 KB, the position of the bad block marker is shifted, and does not appear in the first position of the spare area of the page. The cache swap feature allows consistent swapping of the actual bad block line with the expected bad block line, and causes the operating system to get the bad block marker in the position where it is expected.

Address: 400E_0000h base + 3F28h offset = 400E_3F28h

Table continues on the next page...

NFC_SECSZ field descriptions (continued)

Field	Description
12–0 SIZE	Size in bytes of one elementary transfer unit For devices with pages of 2KB and smaller, this is the physical size of the page in bytes (data bytes + ECC bytes) transferred in one page. When pages are larger than 2KB, they must be split in multiple virtual pages. In this case, the sector size is the size of the virtual page. The virtual page size is the physical size divided by the splitting factor, NFC_CFG[PAGECNT]. **NOTE:** If only a part of a page to be programmed or read, SIZE can be set to the number of affected bytes, not the page size. Then, ECC and DMA (data bytes) are all performed on the number of bytes, indicated by SIZE. **NOTE:** For 16-bit data width flash devices, only odd SIZE is supported. If SIZE is even number, the real implemented size is SIZE – 1. So, write size + 1 to this field. For example, if SIZE = 1, no data is written or read. **NOTE:** When programming NAND memory for boot and using the ECC feature, ensure that SIZE is equal to number of (data + ECC bytes).

31.3.13 Flash configuration (NFC_CFG)

NOTE

NFC_CFG[BTMD] resets to 0 if no boot is performed by the NFC; 1 if booting from NFC.

Address: 400E_0000h base + 3F30h offset = 400E_3F30h

NFC_CFG field descriptions

Field	Description
31 STOPWERR	Stopping on write error

Table continues on the next page...

NFC_CFG field descriptions (continued)

Field	Description
	0 No stop on write error 1 Auto-sequencer stops on a write error
30–22 ECCAD[11:3]	Byte address in SRAM where ECC status is written. **NOTE** ECCAD[2:0] are always zeros
21 ECCSRAM	Writing ECC status to SRAM 0 Do not write ECC status to SRAM 1 Write ECC status to SRAM
20 DMAREQ	Transferring sectors after ECC 0 Do not transfer sector after ECC is done 1 After ECC is done, transfer sector using DMA
19–17 ECCMODE	ECC type 000 No correction, ECC bypass 001 4-error correction (8 ECC bytes) 010 6-error correction (12 ECC bytes) 011 8-error correction (15 ECC bytes) 100 12-error correction (23 ECC bytes) 101 16-error correction (30 ECC bytes) 110 24-error correction (45 ECC bytes) 111 32-error correction (60 ECC bytes)
16 FAST	See the "Fast Flash Configuration for EDO" section for more details. 0 Slow flash timing. Clock in read data on rising edge of read strobe 1 Fast flash timing. Clock in read data a half clock later than rising edge of read strobe
15–13 IDCNT	Number of bytes that are read for the read id command.
12–8 TIMEOUT	The number of flash_clk cycles from NFC_WE high to either: • NAND flash busy (t_{WB}), or • NFC_RE low (t_{WHR}) After the last command is issued to flash, before sampling NFC_R/ $\overline{B}$, the NFC must wait t_{WB} clocks. After t_{WB} clocks: • if NFC_R/ $\overline{B}$ is sampled as high, the NFC considers the command to be a timeout, and the flash memory is idle. The NFC can issue new commands to the flash memory. • if NFC_R/ $\overline{B}$ is sampled as low, the NAND flash memory is busy. When reading the status or ID from the NAND flash memory, after the last command is issued to flash, the NFC must wait for t_{WHR} cycles. The NFC then negates NFC_RE to low to read the valid status or ID. **NOTE:** t_{WB} exists in page program/read, block erase, etc. Refer to the NAND flash datasheet for details of t_{WB} and t_{WHR} .
7 BITWIDTH	Flash mode width 0 8-bit wide flash mode 1 16-bit wide flash mode

Table continues on the next page...

Field	Description
26 CMDBUSY	Command busy Set it command execution busy, cleared otherwise.
25 RESBUSY	Residue engine busy Set if residue engine busy, cleared otherwise.
24 ECCBUSY	ECC engine busy Set if ECC engine busy, cleared otherwise.
23 DMABUSY	DMA engine busy Set if DMA engine busy, cleared otherwise.
22 WERREN	Enable bit for NFC_ISR[WERR]
21 DONEEN	Enable bit for NFC_ISR[DONE]
20 IDLEEN	Enable bit for NFC_ISR[IDLE]
19 WERRCLR	Clear bit for NFC_ISR[WERR]. Writing 1 to this bit clears NFC_ISR[WERR].
18 DONECLR	Clear bit for NFC_ISR[DONE]. Writing 1 to this bit clears NFC_ISR[DONE].
17 IDLECLR	Clear bit for NFC_ISR[IDLE]. Writing 1 to this bit clears NFC_ISR[IDLE].
16–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–4 RESBN	Residue buffer number Buffer number corresponding with the current residue block task.
3–2 ECCBN	ECC buffer number Buffer number corresponding with the current ECC task.
1–0 DMABN	DMA buffer number Buffer number corresponding with the current DMA task.

31.4 Functional Description

The NFC executes commands on a single or bank of external NAND flash chips. The NFC supports commands such as read, program, reset, erase, status read, read ID.

The NFC block contains a DMA engine and built-in ECC logic. For each read or write, the NFC performs ECC calculations on-the-fly. Two DMA channels are organized for each read or write: one for the main area, and one for the spare area. It is possible to disable the second DMA channel, and transfer main and spare data with only the first DMA channel.

Page size supported is 512, 2K, 4K, 8K and 16K bytes. There are 8 different ECC settings provided: 0, 4, 6, 8, 12, 16, 24 and 32 bits errors. They use 0, 8, 12, 15, 23, 30, 45 and 60 ECC bytes. The ECC works on page sizes of 512+spares bytes, 1K+spares bytes, 2K+spares bytes. The ECC algorithm used is a BCH code.

The error corrector can write ECC status to the spare area, since the read is pipelined. This means, while the current page is transferred from flash to buffer, the previous page is ECC corrected, and the page before that is transferred using DMA. Because of the pipelining, it is difficult to inform the CPU in the foreground of ECC errors. To solve this, ECC status is written to the auxiliary area of the sector, and transferred to memory. See Error Corrector Status for more information. It's up to the CPU to inspect the ECC result in memory, and act appropriately.

As described, reads are pipelined. However, writes are flow-through; no advance operations are done during a write. If there is a problem found during a write, the command sequence may be interrupted, and the CPU is informed.

Each page read, page write, page erase, read ID, or read status command sequence needs CPU attention only once. The CPU needs to prepare the DMA to point to the data, write correct values to all registers, and start the command. After command completion, the NFC block may interrupt the CPU.

The block allows command repeat, which is useful for write, read and erase, and allows processing multiple pages with just one command given by the CPU. No bank interleaving is supported during command repeat.

Booting from NAND flash is optional, and how it is activated is device-specific. See the Chip Configuration details for how to activate NFC boot on your device.

If boot feature is activated, first the NFC issues a reset command (0xFF) to the flash, then NFC reads four pages from block 0. Each page is 1056 bytes. The boot pages are protected by 32-bit error correction, which means that of the 1056 bytes, 996 bytes are user bytes and 60 bytes are ECC bytes. When the data from the boot pages is read, successfully error corrected, and stored in the NFC SRAM, the NFC indicates to the CPU that its boot code is visible in the NFC SRAM, and visible on addresses 0x000 to 0xF8F (3984 bytes total).

If the boot image from block 0 cannot be corrected, because there are more than 32 errors in one or several pages, boot is retried on the blocks at row addresses 256, 512, and 768. If it still fails after these retries, boot from the NFC is aborted. The device may begin execution using other memory. See the relevant Chip Configuration section for details on how your device behaves in this scenario.

Right after boot, a special address hashing function is active on all reads and writes DONE to NFC SRAM. This hashing function interleaves the page data from the four boot pages in such a way that all user data is visible in address range 0x000 to 0xF8F instead of four different ranges, one for each page. This hashing is controlled by NFC_CFG[BTMD], and the hashing should be turned off by the CPU after finishing reading/executing the boot image, and before normal operations of the NFC. See Figure 31-25 and NFC Buffer Memory Space.

Page size at boot is set to 1056 bytes to be compatible with a large number of NFC devices, without needing additional power-on reset flags to indicate the boot device.

- Compatible with 8-wide SLC and MLC devices with page size of 2 KB + 64 bytes spare
- Compatible with 8-wide SLC and MLC devices with page size of 4 KB and larger
- Compatible with 16-wide SLC and MLC devices with page size of 2 KB + 64 bytes spare
- Compatible with 16-wide SLC and MLC devices with page size of 4 KB and larger
- Not compatible with devices with 512 bytes page size.

31.4.1 NFC Buffer Memory Space

The next figure shows the organization of the buffer memory space in the NFC. The memory's size is 1152 × 64 bit, and is separated into four buffers, each with incontinuous physical address. For example, buffer 0's physical address is (0x000 + 0x20×i) – (0x007+0x20×i).

However, when the CPU writes or reads a buffer in non-boot mode, the CPU address is continuous, since there's an address transition inside NFC: sram_physical_addr[13:3] = {cpu_addr[11:3],cpu_addr[13:12]}

So, in non-boot mode, the address ranges are:

- Buffer 0: 0x0000 – 0x08FF
- Buffer 1: 0x1000 – 0x18FF

- Buffer 2: 0x2000 – 0x28FF
- Buffer 3: 0x3000 – 0x38FF

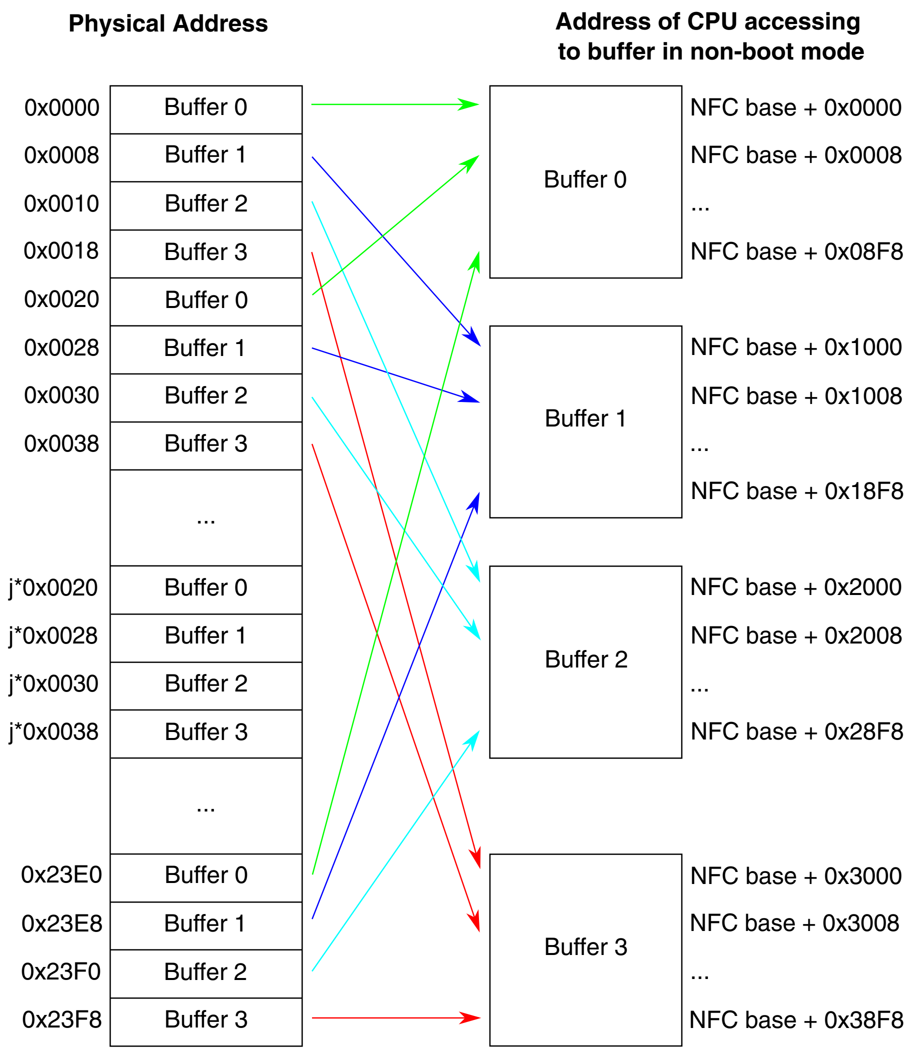

Figure 31-17. NFC Buffer Memory Space

31.4.2 Error Corrector Status

The ECC engine determines if a page is correctable. If correctable, it corrects error bits, and indicates error number. Otherwise, CORFAIL bit is asserted as shown in the next table. For a bad block management strategy to work, it may be necessary for the processor to obtain this information.

The error corrector writes the status word to a byte location to the SRAM buffer, defined by NFC_CFG[ECCAD]. It is selectable if the status is written or not with NFC_CFG[ECCSRAM]. If the status is written to the SRAM buffer, it becomes

effectively part of the flash data, and is processed like the flash data. Most likely, the status byte is written to memory as part of the page header. Once in memory, the ECC status is visible to the CPU, while CPU parses the rest of the flash header. No interrupt on error or status is available because this increases the interrupt load on the CPU. (The interrupt would be independent of the command done interrupt.) It is not possible to stop reading when ECC fails.

The organization of the status byte is shown here.

Table 31-18. ECC Status Word

Field	Definition
7 CORFAIL	0 Page has been successfully corrected 1 Page is uncorrectable
5–0 ERROR_COUNT	Number of errors that have been corrected in this page

NOTE

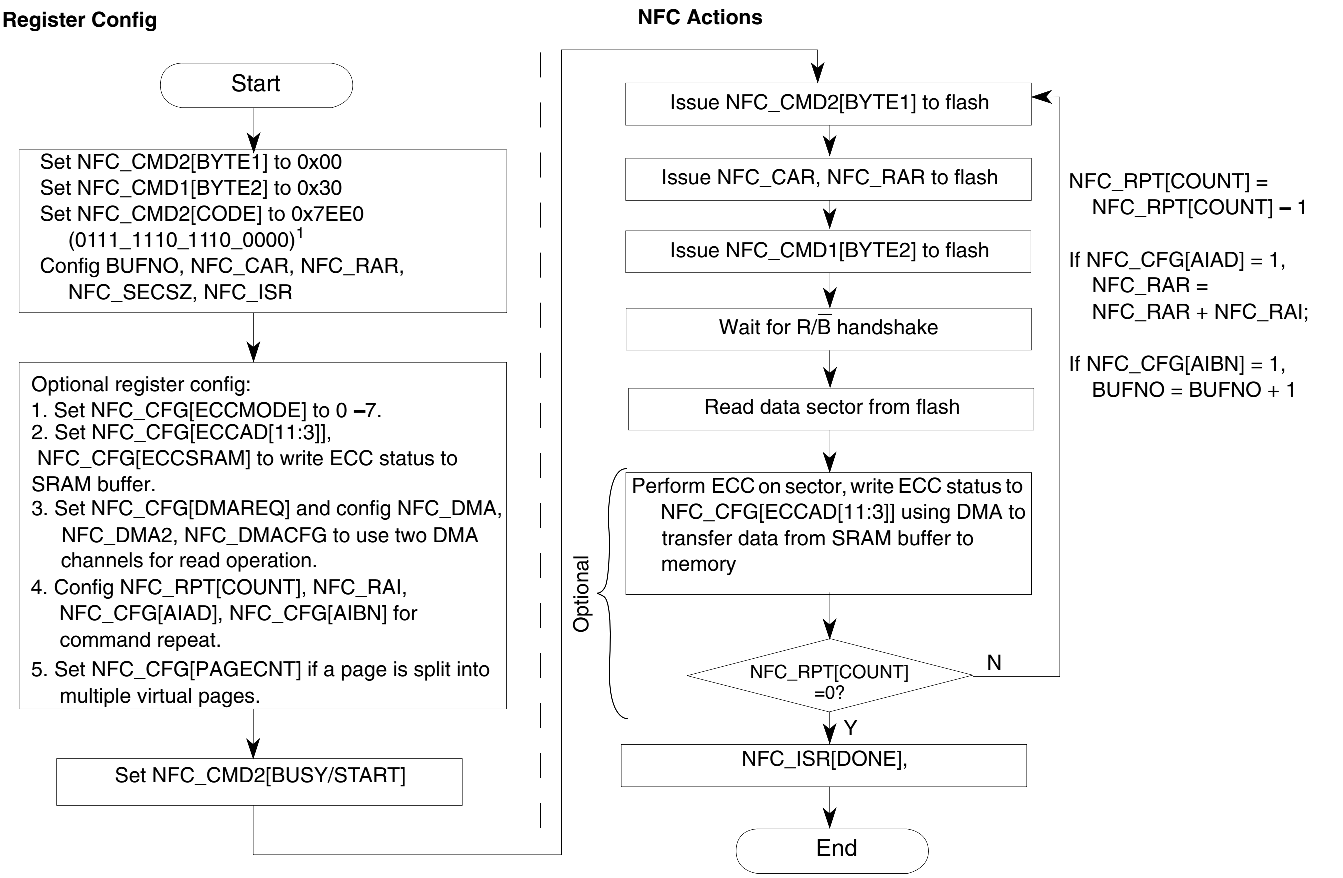
The address of the ECC status byte = Buffer n's start address + ECCAD[11:0] + 7 (n=0,1,2,3).

31.4.3 NFC Basic Commands

NFC basic commands include Page Read, Page Program, Block Erase, Read ID, and Reset.

31.4.3.1 Page Read

This command reads pages from the NAND flash. This figure shows the general flowchart of a read operation.



Note:
1 COL_ADDR2, NFC_RAR[BYTE3], and NFC_CMD1[BYTE2] (bold) are not necessary for some flash devices. See their data sheets for detail. For example:

If the flash only has one column address, then NFC_CMD2[CODE] = 0110_1110_1110_0000;
If the flash only has two row addresses, then NFC_CMD2[CODE] = 0111_1100_1110_0000;
If flash does not need the second command 0x30 for read, then NFC_CMD2[CODE] = 0110_1110_0110_0000.

Figure 31-18. Flow Chart of Read Operation

The next figure shows a particular case: one page is split into 8 virtual pages (see Organization of the Data in the NAND Flash), and DMA is not used. The SRAM buffer can hold data for four (virtual) pages at most. The CPU must transfer data out of the SRAM buffer after the first four virtual pages are read from flash. Otherwise, the next four virtual pages data overwrite the buffer. So, the read operation has following steps:

- Configure registers as shown in the preceding figure. NFC_CFG[PAGECNT] = 4, start commands, wait for NFC_ISR[DONE]
- CPU reads data from buffer, set NFC_CMD2[CODE] = 0x20 (only enable read data)
- Start commands to read out the next 4 virtual pages, wait for NFC_ISR[DONE]

If DMA is used to transfer data from SRAM buffer to memory instead of CPU, the flow in the preceding figure is used: set NFC_CFG[PAGECNT] = 8, set NFC_CFG[DMAREQ] = 1, configure DMA registers, start commands. A pipeline (Functional Description) controls the read operation.

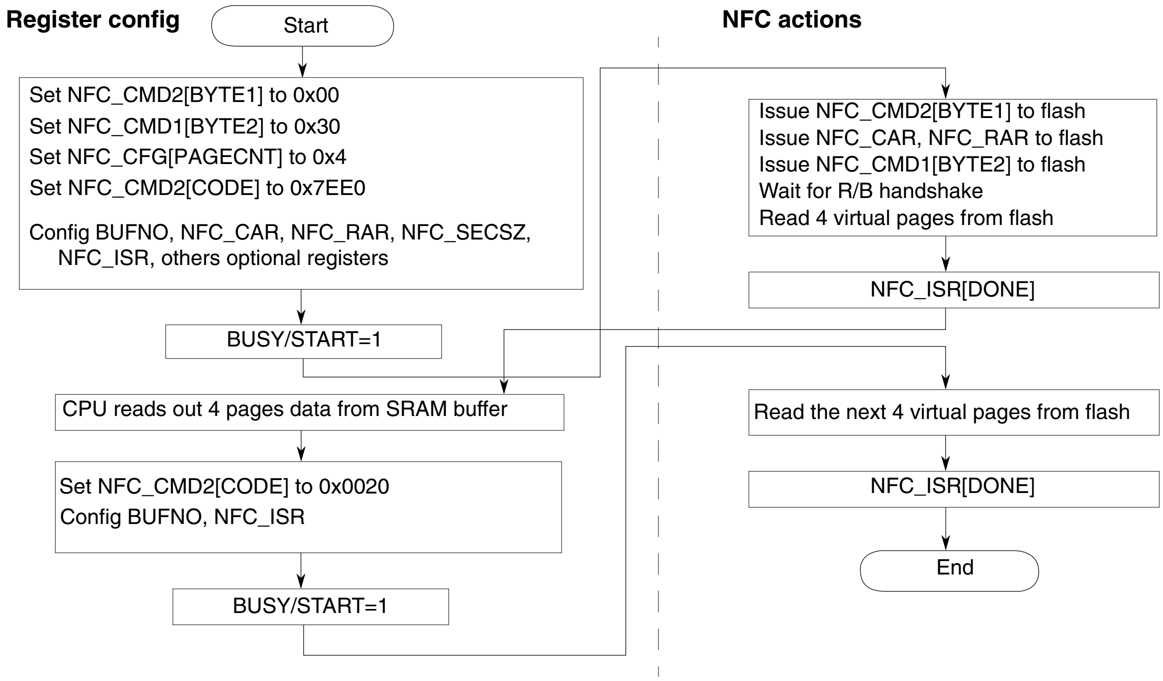


Figure 31-19. Flow Chart of Read Operation, NFC_CFG[PAGECNT] = 8, No DMA

Note

See footnote in Figure 31-18.

31.4.3.2 Page Program

This command programs pages to the NAND flash. The next figure is the general flow of page program operation.

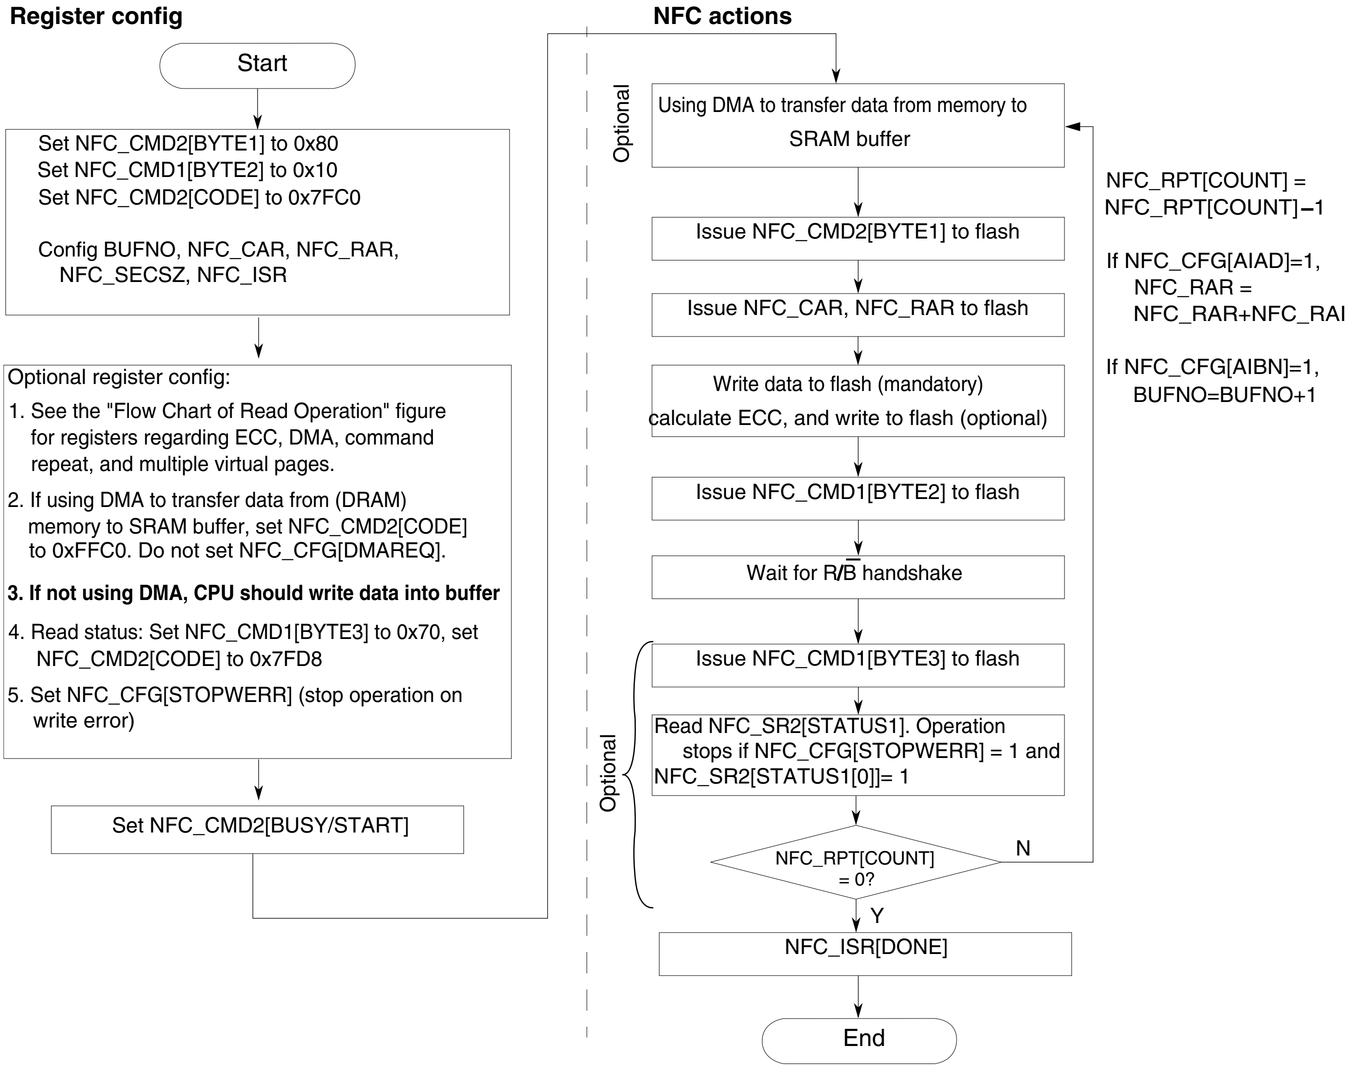

Figure 31-20. Flow Chart of Page Program Operation

Note

COL_ADDR2 and NFC_RAR[BYTE3] (bold) are not necessary for some flash devices. See their data sheets for detail. See the footnote of Figure 31-18.

The next figure shows the particular case which is similar to Figure 31-19. The CPU writes at most four virtual pages of data into the buffer before the first start command. Set NFC_CFG[PAGECNT] to 4 and set NFC_CMD2[CODE] twice:

- First, set it to 0x7F00 (0111_1111_0000_0000). The NFC issues NFC_CMD2[BYTE1], address cycles, four virtual pages data to flash. After NFC_ISR[DONE] is set, the CPU can write the next four virtual pages data into the SRAM buffer.
- Second, set CODE to 0x01C0 (0000_0001_1100_0000). The NFC sends the next four virtual pages of data to flash, issues NFC_CMD1[BYTE2], waits for R/$\overline{B}$ handshake, and waits for NFC_ISR[DONE] to set.

Like the read operation, if DMA transfers data from memory to NFC SRAM buffer (instead of the CPU), the flow in the preceding figure is used and set NFC_CFG[PAGECNT] to 0x8.

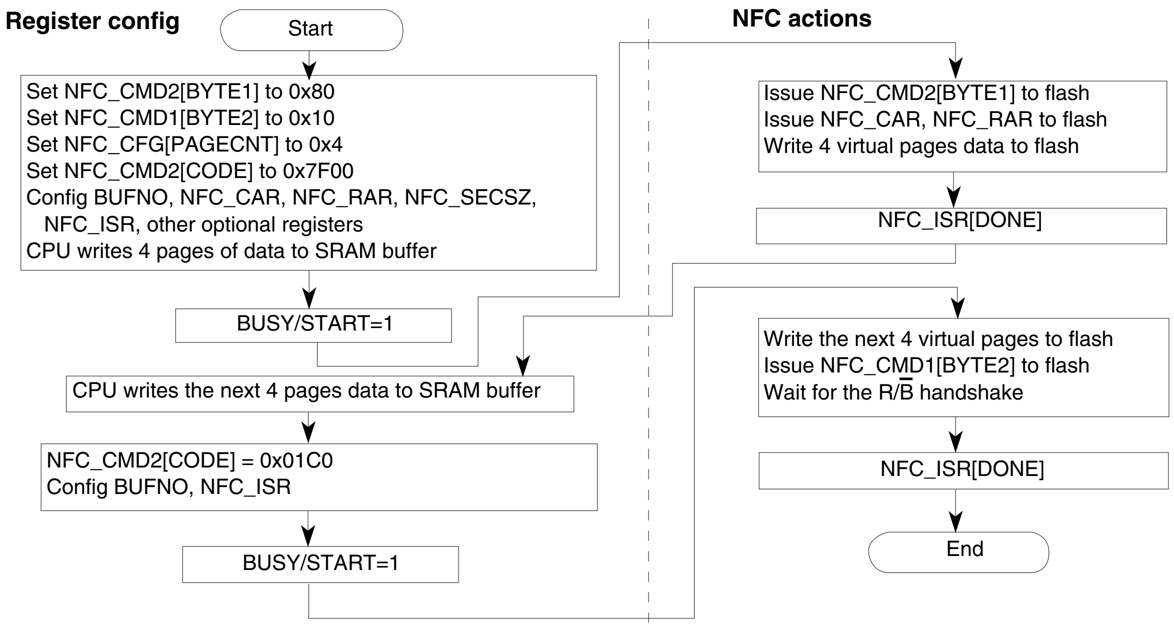

Figure 31-21. Flow Chart of Page Program Operation, NFC_CFG[PAGECNT] = 8, No DMA

Note

If you want to read the status after the second 0x10 command, set NFC_CMD1[BYTE3] to 0x70 and NFC_CMD2[CODE] to 0x01D8 (0000_0001_1101_1000). Then, after "Wait for the R/$\overline{B}$ handshake", the NFC issues NFC_CMD1[BYTE3] to flash, and reads the status. If NFC_CFG[STOPWERR] is set and NFC_SR2[STATUS1[0]]=1, operation stops. Otherwise, NFC_ISR[DONE] comes out. The COL_ADDR2 and NFC_RAR[BYTE3] of the first NFC_CMD2[CODE] may not be necessary. See note 1 of Figure 31-18.

31.4.3.3 Block Erase

This command is used to erase blocks.

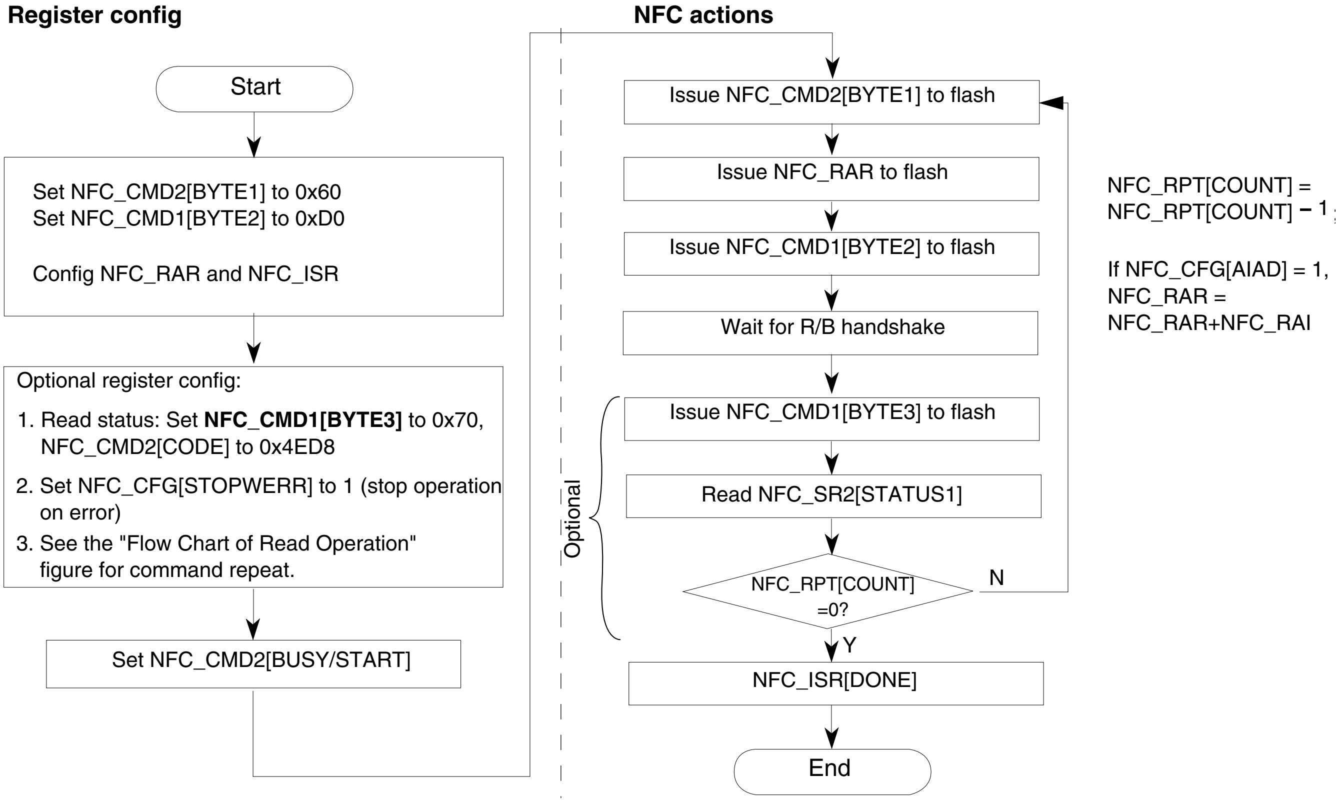

Figure 31-22. Flow Chart of Block Erase Operation

Note

NFC_RAR[BYTE3] (bold) is not necessary for some flash devices. See their data sheets for detail.

Note

If NFC_CFG[STOPWERR] is set and NFC_SR2[STATUS1[0]]=1, operation stops.

31.4.3.4 Read ID

This command reads the flash ID.

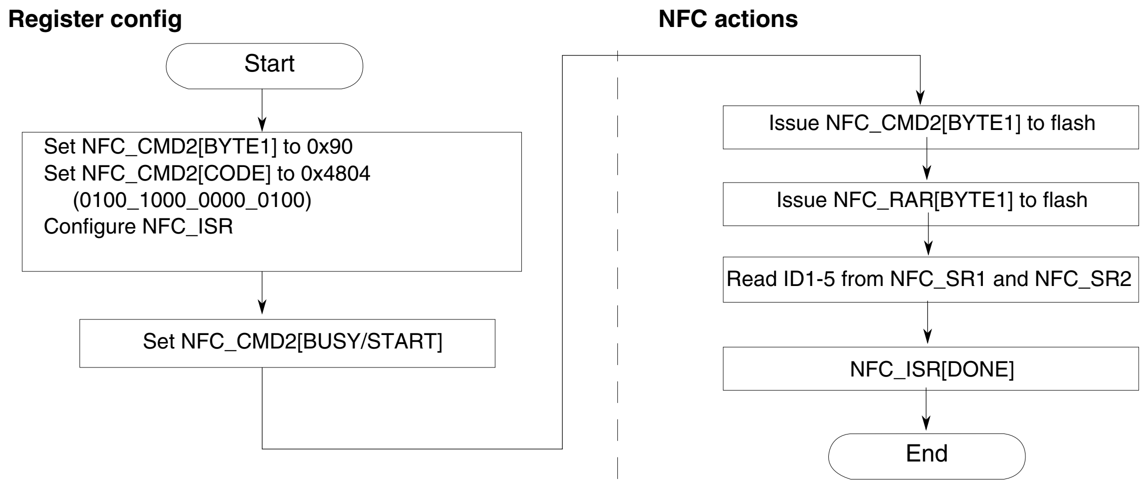

Figure 31-23. Flow Chart of Read ID Operation

31.4.3.5 Reset

This command sends a single reset command to the flash.

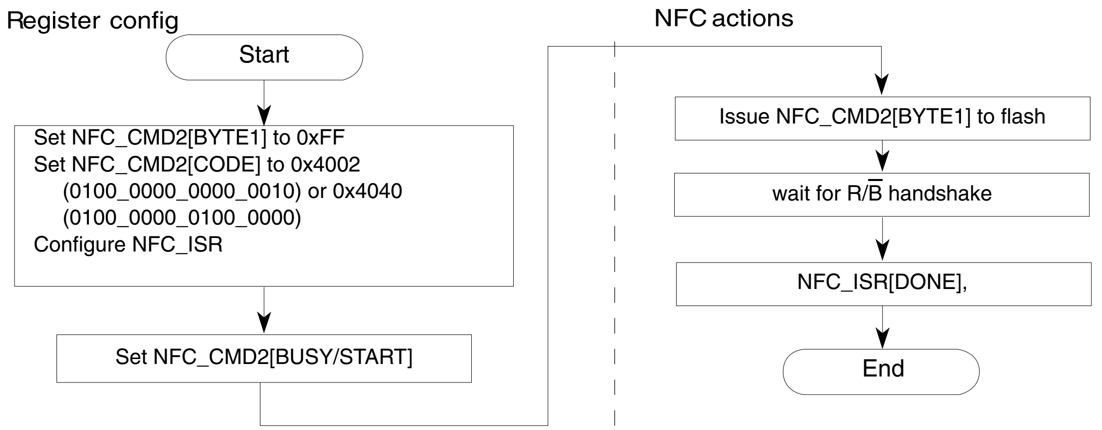

Figure 31-24. Flow Chart of Reset Operation

31.4.4 NAND Flash Boot

For booting, the power-on reset values of some registers are:

- Sector size is 1056 bytes: NFC_SECSZ = 1056
- Flash is defined as 8-bit: NFC_CFG[16BIT] = 0
- ECC correction depth is 32 bits errors: NFC_CFG[ECCMODE] = 0x7
- Boot sector address is 0: NFC_CMD2[BUFNO] = 00

Boot-up occurs after power-on reset. After boot, the following happens:

1. The NFC issues reset command 0xFF to the flash.
2. Four boot blocks are identified in the flash at row addresses 0, 256, 512, and 768.
3. The flash controller burst reads four pages from the first boot block to memory. A total of 4 KB are read in this way.
4. If there is no ECC failure during the burst read, the boot is successful.

   If there is an ECC failure during the burst read, the process is started again from the next boot block. If the fourth block still has ECC failure, boot is unsuccessful, which means it is not possible to read a reliable boot image from the flash.
5. CPU access is held until boot completion.
6. After boot, the boot image is visible in the memory map at address 0x00 – 0xF8F. A special hash function is active on the NFC SRAM read to have the boot image in one continuous address range, and not in four address ranges (one for each page). The NFC_CFG[BTMD] bit controls this hash function, and this bit should be cleared after the CPU has read/executed the boot image, and before it operates the NFC in standard mode. See the next figure.

Note

There is no difference in how data is transferred between SRAM buffer and the flash: one page uses one buffer. But, how the CPU writes/reads the buffer is different. In non-boot mode, the write/read address is the SRAM physical address. In boot mode, the write/read address is based on the buffers. See NFC Buffer Memory Space.

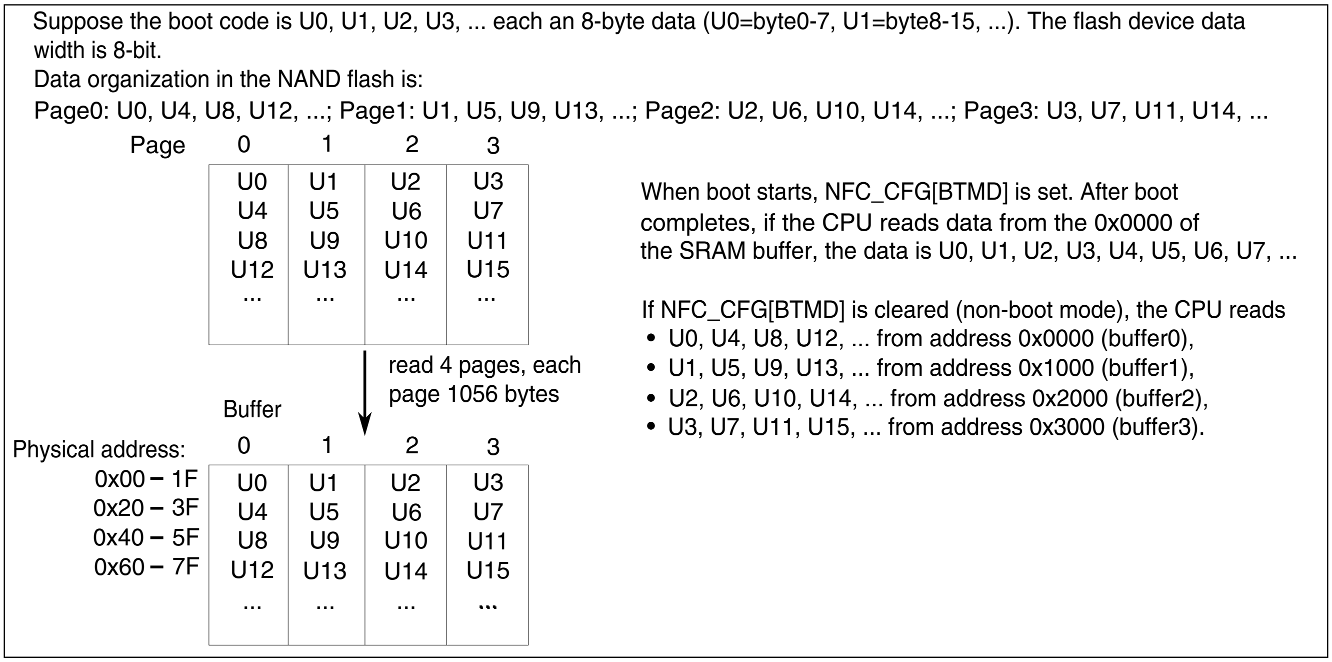

Figure 31-25. Boot and NFC_CFG[BTMD]

The CPU boot code should be split into four pages as shown in the preceding figure. Boot sector encoding cannot be done by the NFC block itself. It must be done in software. Each page contains 996-byte boot codes and 60-byte ECC codes.

The ECC codes should be inverted because when NFC is doing a page program, it sends the inverted ECC codes to flash. When reading, it inverts them again to get the correct ECC codes for error correction. And only page reads are performed in boot operation. So, software should do the ECC code inversion after boot sector encoding.

The boot is identical for a 8- and 16-bit wide flash. If a 16-bit flash is connected, the data on the upper lane is discarded. If a 8-bit flash is connected, the upper 1 KB of data is not read.

For an 8-bit flash, the upper 1 KB of data is not read.

Table 31-19. Boot Data's Location in a Page — 8-bit

31.4.5 Fast Flash Configuration for EDO

Normally, read out data goes valid after the high-to-low transition of $\overline{RE}$, and invalid on the low-to-high transition (as shown in the next figure) $t_{RHOH}<t_{REH}$. NFC sampled the read data at the negedge of flash_clk, and because the data is invalid at that time, a latch is used here to maintain the valid data during the high period of flash_clk, so that NFC can sample correct data.

Some flash devices contain an EDO (enhanced data out) feature, where the data can be held until the next high-to-low $\overline{RE}$ transition (see the figure after next, labeled "Read Operation, EDO type"), $t_{RHOH}>t_{REH}$. The read data is valid at the negedge of flash_clk, NFC can sample data directly without latching it. To support the EDO feature, the NFC must work in fast mode (NFC_CFG[FAST] set). The NFC clock must be configured fast enough (usually > 33 MHz) according to the data sheet of flash devices.

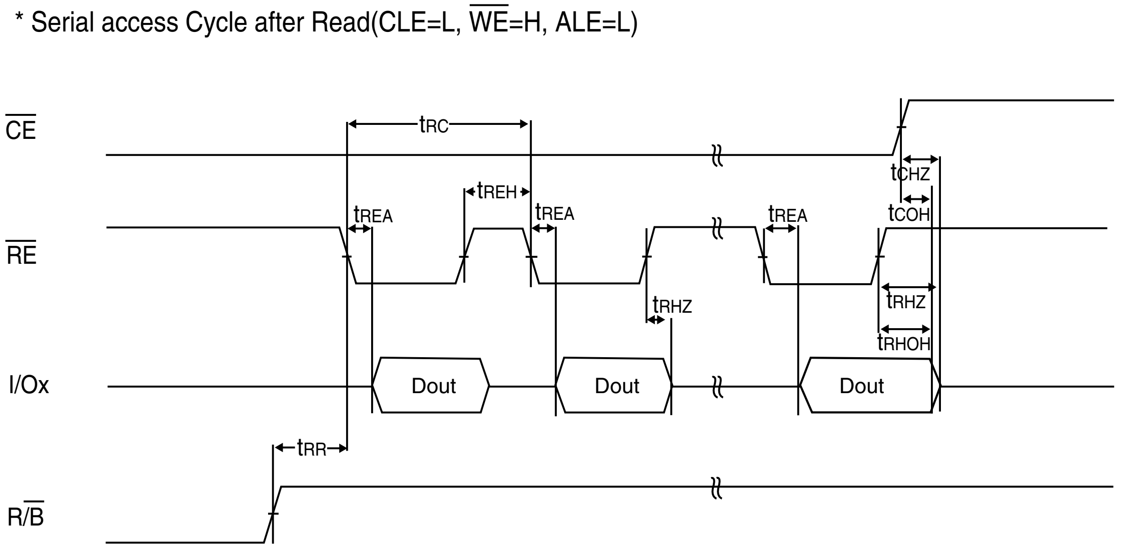

Figure 31-26. Read Operation

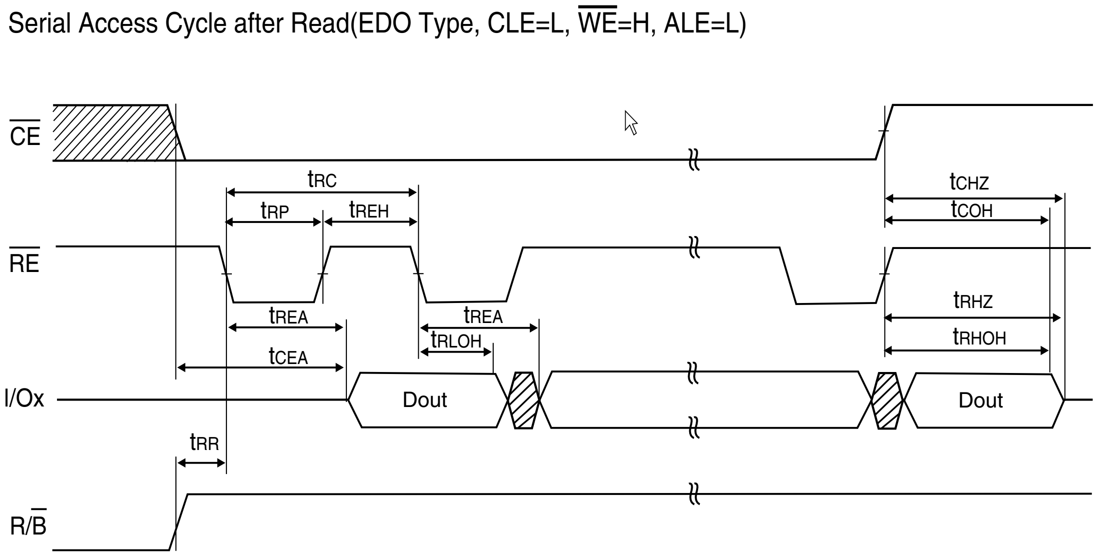

Figure 31-27. Read Operation, EDO type

31.4.6 Organization of the Data in the NAND Flash

Pages on the flash can be split into multiple virtual ECC/DMA pages. The parameter that controls this is NFC_CFG[PAGECNT]. This parameter gives the number of virtual ECC/DMA pages in one flash page.

The virtual page is split into a user (main) area and ECC (spare) area. Data in the user area can be set or used by the application, while data in the ECC area is set and used by the ECC.

The following tables give virtual-to-physical mappings for various flash devices and their recommended settings.

Table 31-21. Virtual-to-Physical Mappings of Different Flash,

Flash page size (main +spare) bytes	NFC_CFG [ECC MODE]	ECC bits	NFC_CFG [PAGE CNT]	Sector size (bytes)	Virtual page user size (bytes)	Mapping

						VirtualPage_6[522:0] = Physical[3750:3228]
						VirtualPage_7[522:0] = Physical[4288:3766]

1. In most applications, this mode is of no use because user size is too small.
2. When 4KB page is split into eight virtual pages, if page program/read using DMA, set NFC_CFG[PAGECNT] to 8. if not using DMA, set NFC_CFG[PAGECNT] to 4. See Page Read and Page Program for details.

If flash devices with a physical page size of 4K or more are used, the bad block marker appears as the first byte of the spare area. But, because of the physical-to-virtual mapping, it does not appear in byte 2048 of the virtual page, where its logical place would be. The DMA engine contains the option to swap some bytes, and to make the bad block marker appear in the requested place.

Table 31-22. Using the Swap Field to Move the Bad Block Marker

Flash sector size (main + spare) bytes	Bad block marker (physical)	Bad block marker (virtual) Before swap	Bad block marker (expected) After swap	Swap
4096 + 128	4096	Page 1/byte 1984	Page 1/byte 2048	NFC_SWAP[ADDR1] = (1984/8)[1]
				NFC_SWAP[ADDR2] = (2048/8)
4096 + 208	4096	Page 1/byte 1944	Page 1/byte 2048	NFC_SWAP[ADDR1] = (1944/8)
				NFC_SWAP[ADDR2] = (2048/8)

1. Only works with a user page size of at least 2055 bytes. Does not work with ECC mode 111.

31.4.7 Flash Command Code Description

The 16-bit command code in NFC_CMD2[CODE] is defined in the next table. If a bit is set, the action is executed. The command is repeated for the number of the NFC_RPT[COUNT] value. If NFC_RPT[COUNT] is zero or one, the command is executed once.

Table 31-23. NFC_CMD2[CODE] Detail

NFC_CMD2 [CODE] bit	Action when Bit is Set
15	Start DMA transfer to read data from memory , and write to SRAM.
14	Send command byte 1 (NFC_CMD2[BYTE1]) to flash
13	Send column address 1 (NFC_CAR[BYTE1]) to flash
12	Send column address 2 (NFC_CAR[BYTE2]) to flash
11	Send row address 1 (NFC_RAR[BYTE1]) to flash
10	Send row address 2 (NFC_RAR[BYTE2]) to flash
9	Send row address 3 (NFC_RAR[BYTE3]) to flash
8	Write data to flash. Total of NFC_CFG[PAGECNT] pages is written to the flash, and equal number of starts is sent to the residue engine. Also, additional starts to the DMA engine are sent, until DMA has transferred the NFC_CFG[PAGECNT] data from memory to NFC.
7	Send command byte 2 (NFC_CMD1[BYTE2]) to flash
6	Wait for flash R/$\overline{B}$ handshake
5	Read data from flash. Read is only started if the new NFC_CMD2[BUFNO] is idle. One or more starts are sent to the residue engine, total NFC_CFG[PAGECNT] starts. **Note:** For reads, DMA is not started. Instead, to start DMA for reads, NFC_CFG[DMAREQ] must be set.
4	Send command byte 3 (NFC_CMD1[BYTE3]) to flash
3	Read flash status
2	Read ID
1	Always set. End-of-command marker used to signal done.
0	Reserved, must be cleared.

31.4.8 Interrupts

There are two interrupts to flag the end of a command execution:

1. The DONE interrupt, NFC_ISR[DONE]. Use this interrupt if commands are sent back-to-back to the flash. It indicates when a new command can be dispatched. The DONE interrupt is given before the flash data is corrected and resident in memory, because the operation of the ECC engine and DMA engine is pipelined.

When the DONE interrupt tracks command completion, the software may also monitor the NFC_ISR[ECCBUSY, DMABUSY, ECCBN, DMABN] fields.

a. NFC_ISR[ECCBUSY] indicates that the ECC block is still busy, and reports the buffer number the ECC block is working on in NFC_ISR[ECCBN].
b. NFC_ISR[DMABUSY] indicates that the DMA block is still busy, and reports the buffer number the DMA block is working on in NFC_ISR[DMABN].

2. The command IDLE interrupt, NFC_ISR[IDLE]. Use this interrupt if you want to use the data produced in the next process. The IDLE interrupt indicates all command processing has terminated, and the relevant data is now available in memory or the NFC SRAM buffer. When using back-to-back reads to the flash, use of the IDLE interrupt means the NFC does not operate at its maximum transfer speed, as ECC and DMA are now done in the foreground.

When using the DONE interrupt, transfer completion for write pages can be assumed when the DONE interrupt is received. When DONE is received for read pages, the data may still be in flight in the DMA or the ECC. To check this, the CPU should remember the buffer number (NFC_CMD2[BUFNO]) associated with the command, and wait until the DMA and ECC are either idle, or are both busy on a different buffer number. (The ECC buffer number and the DMA buffer number fields do not match the BUFNO specified with the command.) You can check on any DONE interrupt or by polling the register.

Chapter 32
External Bus Interface (FlexBus)

32.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

This chapter describes external bus data transfer operations and error conditions. It describes transfers initiated by the core processor (or any other bus master) and includes detailed timing diagrams showing the interaction of signals in supported bus operations.

32.1.1 Definition

The FlexBus multifunction external bus interface controller is a hardware module that:

- Provides memory expansion and provides connection to external peripherals with a parallel bus
- Can be directly connected to the following asynchronous or synchronous slave-only devices with little or no additional circuitry:
  - External ROMs
  - Flash memories
  - Programmable logic devices
  - Other simple target (slave) devices

32.1.2 Features

FlexBus offers the following features:

- Five independent, user-programmable chip-select signals ($\overline{\text{FB_CS}}$4 –$\overline{\text{FB_CS}}$0)
- 8-bit, 16-bit, and 32-bit port sizes with configuration for multiplexed or nonmultiplexed address and data buses
- 8-bit, 16-bit, 32-bit, and 16-byte transfers
- Programmable burst and burst-inhibited transfers selectable for each chip-select and transfer direction
- Programmable address-setup time with respect to the assertion of a chip-select
- Programmable address-hold time with respect to the deassertion of a chip-select and transfer direction
- Extended address latch enable option to assist with glueless connections to synchronous and asynchronous memory devices

32.2 Signal descriptions

This table describes the external signals involved in data-transfer operations.

NOTE

Not all of the following signals may be available on a particular device. See the Chip Configuration details for information on which signals are available.

Table 32-1. FlexBus signal descriptions

Signal	I/O	Function
FB_A31–FB_A0	O	Address Bus When FlexBus is used in a nonmultiplexed configuration, this is the address bus. When FlexBus is used in a multiplexed configuration, this bus is not used.
FB_D31–FB_D0	I/O	Data Bus—During the first cycle, this bus drives the upper address byte, addr[31:24]. When FlexBus is used in a nonmultiplexed configuration, this is the data bus, FB_D. When FlexBus is used in a multiplexed configuration, this is the address and data bus, FB_AD. The number of byte lanes carrying the data is determined by the port size associated with the matching chip-select. When FlexBus is used in a multiplexed configuration, the full 32-bit address is driven on the first clock of a bus cycle (address phase). After the first clock, the data is driven on the bus (data phase). During the data phase, the address is driven on the pins not used for data. For example, in 16-bit mode, the lower address is driven on FB_AD15–FB_AD0, and in 8-bit mode, the lower address is driven on FB_AD23–FB_AD0.

Table continues on the next page...

Table 32-1. FlexBus signal descriptions (continued)

Signal	I/O	Function
FB_CS4–FB_CS0	O	General Purpose Chip-Selects—Indicate which external memory or peripheral is selected. A particular chip-select is asserted when the transfer address is within the external memory's or peripheral's address space, as defined in CSAR[BA] and CSMR[BAM].
FB_BE_31_24 FB_BE_23_16 FB_BE_15_8 FB_BE_7_0	O	Byte Enables—Indicate that data is to be latched or driven onto a specific byte lane of the data bus. CSCR[BEM] determines if these signals are asserted on reads and writes or on writes only. For external SRAM or flash devices, the FB_BE outputs should be connected to individual byte strobe signals.
FB_OE	O	Output Enable—Sent to the external memory or peripheral to enable a read transfer. This signal is asserted during read accesses only when a chip-select matches the current address decode.
FB_R/W	O	Read/Write—Indicates whether the current bus operation is a read operation (FB_R/W high) or a write operation (FB_R/W low).
FB_TS	O	Transfer Start—Indicates that the chip has begun a bus transaction and that the address and attributes are valid. An inverted FB_TS is available as an address latch enable (FB_ALE), which indicates when the address is being driven on the FB_AD bus. FB_TS/FB_ALE is asserted for one bus clock cycle. The chip can extend this signal until the first positive clock edge after FB_CS asserts. See CSCR[EXTS] and Extended Transfer Start/Address Latch Enable.
FB_ALE	O	Address Latch Enable—Indicates when the address is being driven on the FB_A bus (inverse of FB_TS).

Table continues on the next page...

Table 32-1. FlexBus signal descriptions (continued)

Signal	I/O	Function
FB_TSIZ1–FB_TSIZ0	O	Transfer Size—Indicates (along with FB_TBST) the data transfer size of the current bus operation. The interface supports 8-, 16-, and 32-bit operand transfers and allows accesses to 8-, 16-, and 32-bit data ports. • 00b = 4 bytes • 01b = 1 byte • 10b = 2 bytes • 11b = 16 bytes (line) For misaligned transfers, FB_TSIZ1–FB_TSIZ0 indicate the size of each transfer. For example, if a 32-bit access through a 32-bit port device occurs at a misaligned offset of 1h, 8 bits are transferred first (FB_TSIZ1–FB_TSIZ0 = 01b), 16 bits are transferred next at offset 2h (FB_TSIZ1–FB_TSIZ0 = 10b), and the final 8 bits are transferred at offset 4h (FB_TSIZ1–FB_TSIZ0 = 01b). For aligned transfers larger than the port size, FB_TSIZ1–FB_TSIZ0 behave as follows: • If bursting is used, FB_TSIZ1–FB_TSIZ0 are driven to the transfer size. • If bursting is inhibited, FB_TSIZ1–FB_TSIZ0 first show the entire transfer size and then show the port size. For burst-inhibited transfers, FB_TSIZ1–FB_TSIZ0 change with each FB_TS assertion to reflect the next transfer size. For transfers to port sizes smaller than the transfer size, FB_TSIZ1–FB_TSIZ0 indicate the size of the entire transfer on the first access and the size of the current port transfer on subsequent transfers. For example, for a 32-bit write to an 8-bit port, FB_TSIZ1–FB_TSIZ0 are 00b for the first transaction and 01b for the next three transactions. If bursting is used for a 32-bit write to an 8-bit port, FB_TSIZ1–FB_TSIZ0 are driven to 00b for the entire transfer.
FB_TBST	O	Transfer Burst—Indicates that a burst transfer is in progress as driven by the chip. A burst transfer can be 2 to 16 beats depending on FB_TSIZ1–FB_TSIZ0 and the port size. **Note:** When a burst transfer is in progress (FB_TBST = 0b), the transfer size is 16 bytes (FB_TSIZ1–FB_TSIZ0 = 11b), and the address is misaligned within the 16-byte boundary, the external memory or peripheral must be able to wrap around the address.

Table continues on the next page...

Table 32-1. FlexBus signal descriptions (continued)

Signal	I/O	Function
FB_TA	I	Transfer Acknowledge—Indicates that the external data transfer is complete. When FB_TA is asserted during a read transfer, FlexBus latches the data and then terminates the transfer. When FB_TA is asserted during a write transfer, the transfer is terminated. If auto-acknowledge is disabled (CSCR[AA] = 0), the external memory or peripheral drives FB_TA to terminate the transfer. If auto-acknowledge is enabled (CSCR[AA] = 1), FB_TA is generated internally after a specified number of wait states, or the external memory or peripheral may assert external FB_TA before the wait-state countdown to terminate the transfer early. The chip deasserts FB_CS one cycle after the last FB_TA is asserted. During read transfers, the external memory or peripheral must continue to drive data until FB_TA is recognized. For write transfers, the chip continues driving data one clock cycle after FB_CS is deasserted. The number of wait states is determined by CSCR or the external FB_TA input. If the external FB_TA is used, the external memory or peripheral has complete control of the number of wait states. **Note:** External memory or peripherals should assert FB_TA only while the FB_CS signal to the external memory or peripheral is asserted. The CSPMCR register controls muxing of FB_TA with other signals. If auto-acknowledge is not used and CSPMCR does not allow FB_TA control, FlexBus may hang.
FB_CLK	O	FlexBus Clock Output

32.3 Memory Map/Register Definition

The following tables describe the registers and bit meanings for configuring chip-select operation.

The actual number of chip selects available depends upon the device and its pin configuration. If the device does not support certain chip select signals or the pin is not configured for a chip-select function, then that corresponding set of chip-select registers has no effect on an external pin.

Note

You must set CSMR0[V] before the chip select registers take effect.

A bus error occurs when writing to reserved register locations.

FB memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4001_E000	Chip Select Address Register (FB_CSAR0)	32	R/W	0000_0000h	32.3.1/1338

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FB_CSAR*n* field descriptions

Field	Description
31–16 BA	Base Address Defines the base address for memory dedicated to the associated chip-select. BA is compared to bits 31–16 on the internal address bus to determine if the associated chip-select's memory is being accessed. **NOTE:** Because the FlexBus module is one of the slaves connected to the crossbar switch, it is only accessible within a certain memory range. See the chip memory map for the applicable FlexBus "expansion" address range for which the chip-selects can be active. Set the CSARn and CSMRn registers appropriately before accessing this region.

Table continues on the next page...

FB_CSAR*n* field descriptions (continued)

Field	Description
15–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

32.3.2 Chip Select Mask Register (FB_CSMR*n*)

Specifies the address mask and allowable access types for the associated chip-select.

Address: 4001_E000h base + 4h offset + (12d × i), where i=0d to 4d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	BAM															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0							WP	0							V
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FB_CSMR*n* field descriptions

Field	Description
31–16 BAM	Base Address Mask Defines the associated chip-select's block size by masking address bits. 0 The corresponding address bit in CSAR is used in the chip-select decode. 1 The corresponding address bit in CSAR is a don't care in the chip-select decode.
15–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 WP	Write Protect Controls write accesses to the address range in the corresponding CSAR. 0 Write accesses are allowed. 1 Write accesses are not allowed. Attempting to write to the range of addresses for which the WP bit is set results in a bus error termination of the internal cycle and no external cycle.
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 V	Valid Specifies whether the corresponding CSAR, CSMR, and CSCR contents are valid. Programmed chip-selects do not assert until the V bit is 1b (except for FB_CS0, which acts as the global chip-select). **NOTE:** At reset, $\overline{\text{FB\_CS0}}$ will fire for any access to the FlexBus memory region. CSMR0[V] must be set as part of the chip select initialization sequence to allow other chip selects to function as programmed.

Table continues on the next page...

FB_CSMRn field descriptions (continued)

Field	Description
	0 Chip-select is invalid. 1 Chip-select is valid.

32.3.3 Chip Select Control Register (FB_CSCRn)

Controls the auto-acknowledge, address setup and hold times, port size, burst capability, and number of wait states for the associated chip select.

NOTE

To support the global chip-select ($\overline{FB\_CS0}$), the CSCR0 reset values differ from the other CSCRs. The reset value of CSCR0 is as follows:

- Bits 31–24 are 0b
- Bit 23–3 are chip-dependent
- Bits 3–0 are 0b

See the chip configuration details for your particular chip for information on the exact CSCR0 reset value.

Address: 4001_E000h base + 8h offset + (12d × i), where i=0d to 4d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

FB_CSCRn field descriptions

Field	Description
31–26 SWS	Secondary Wait States Used only when the SWSEN bit is 1b. Specifies the number of wait states inserted before an internal transfer acknowledge is generated for a burst transfer (except for the first termination, which is controlled by WS).

Table continues on the next page...

FB_CSCR*n* field descriptions (continued)

Field	Description
25–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23 SWSEN	Secondary Wait State Enable 0 Disabled. A number of wait states (specified by WS) are inserted before an internal transfer acknowledge is generated for all transfers. 1 Enabled. A number of wait states (specified by SWS) are inserted before an internal transfer acknowledge is generated for burst transfer secondary terminations.
22 EXTS	Extended Transfer Start/Extended Address Latch Enable Controls how long $\overline{\text{FB\_TS}}$ /FB_ALE is asserted. 0 Disabled. $\overline{\text{FB\_TS}}$ /FB_ALE asserts for one bus clock cycle. 1 Enabled. $\overline{\text{FB\_TS}}$ /FB_ALE remains asserted until the first positive clock edge after $\overline{\text{FB\_CSn}}$ asserts.
21–20 ASET	Address Setup Controls when the chip-select is asserted with respect to assertion of a valid address and attributes. 00 Assert $\overline{\text{FB\_CSn}}$ on the first rising clock edge after the address is asserted (default for all but $\overline{\text{FB\_CS0}}$). 01 Assert $\overline{\text{FB\_CSn}}$ on the second rising clock edge after the address is asserted. 10 Assert $\overline{\text{FB\_CSn}}$ on the third rising clock edge after the address is asserted. 11 Assert $\overline{\text{FB\_CSn}}$ on the fourth rising clock edge after the address is asserted (default for $\overline{\text{FB\_CS0}}$).
19–18 RDAH	Read Address Hold or Deselect Controls the address and attribute hold time after the termination during a read cycle that hits in the associated chip-select's address space. **NOTE:** • The hold time applies only at the end of a transfer. Therefore, during a burst transfer or a transfer to a port size smaller than the transfer size, the hold time is only added after the last bus cycle. • The number of cycles the address and attributes are held after $\overline{\text{FB\_CSn}}$ deassertion depends on the value of the AA bit. 00 When AA is 0b, 1 cycle. When AA is 1b, 0 cycles. 01 When AA is 0b, 2 cycles. When AA is 1b, 1 cycle. 10 When AA is 0b, 3 cycles. When AA is 1b, 2 cycles. 11 When AA is 0b, 4 cycles. When AA is 1b, 3 cycles.
17–16 WRAH	Write Address Hold or Deselect Controls the address, data, and attribute hold time after the termination of a write cycle that hits in the associated chip-select's address space. **NOTE:** The hold time applies only at the end of a transfer. Therefore, during a burst transfer or a transfer to a port size smaller than the transfer size, the hold time is only added after the last bus cycle. 00 1 cycle (default for all but $\overline{\text{FB\_CS0}}$) 01 2 cycles 10 3 cycles 11 4 cycles (default for $\overline{\text{FB\_CS0}}$)
15–10 WS	Wait States

Table continues on the next page...

FB_CSCR*n* field descriptions (continued)

Field	Description
	Specifies the number of wait states inserted after FlexBus asserts the associated chip-select and before an internal transfer acknowledge is generated (WS = 00h inserts 0 wait states, ..., WS = 3Fh inserts 63 wait states).
9 BLS	Byte-Lane Shift Specifies if data on FB_AD appears left-aligned or right-aligned during the data phase of a FlexBus access. 0 Not shifted. Data is left-aligned on FB_AD. 1 Shifted. Data is right-aligned on FB_AD.
8 AA	Auto-Acknowledge Enable Asserts the internal transfer acknowledge for accesses specified by the chip-select address. **NOTE:** If AA is 1b for a corresponding FB_CSn and the external system asserts an external $\overline{\text{FB\_TA}}$ before the wait-state countdown asserts the internal FB_TA, the cycle is terminated. Burst cycles increment the address bus between each internal termination. **NOTE:** This field must be 1b if CSPMCR disables FB_TA. 0 Disabled. No internal transfer acknowledge is asserted and the cycle is terminated externally. 1 Enabled. Internal transfer acknowledge is asserted as specified by WS.
7–6 PS	Port Size Specifies the data port width of the associated chip-select, and determines where data is driven during write cycles and where data is sampled during read cycles. 00 32-bit port size. Valid data is sampled and driven on FB_D[31:0]. 01 8-bit port size. Valid data is sampled and driven on FB_D[31:24] when BLS is 0b, or FB_D[7:0] when BLS is 1b. 1X 16-bit port size. Valid data is sampled and driven on FB_D[31:16] when BLS is 0b, or FB_D[15:0] when BLS is 1b.
5 BEM	Byte-Enable Mode Specifies whether the corresponding $\overline{\text{FB\_BE}}$ is asserted for read accesses. Certain memories have byte enables that must be asserted during reads and writes. Write 1b to the BEM bit in the relevant CSCR to provide the appropriate mode of byte enable support for these SRAMs. 0 $\overline{\text{FB\_BE}}$ is asserted for data write only. 1 $\overline{\text{FB\_BE}}$ is asserted for data read and write accesses.
4 BSTR	Burst-Read Enable Specifies whether burst reads are enabled for memory associated with each chip select. 0 Disabled. Data exceeding the specified port size is broken into individual, port-sized, non-burst reads. For example, a 32-bit read from an 8-bit port is broken into four 8-bit reads. 1 Enabled. Enables data burst reads larger than the specified port size, including 32-bit reads from 8- and 16-bit ports, 16-bit reads from 8-bit ports, and line reads from 8-, 16-, and 32-bit ports.
3 BSTW	Burst-Write Enable Specifies whether burst writes are enabled for memory associated with each chip select.

Table continues on the next page...

FB_CSCR*n* field descriptions (continued)

Field	Description
	0 Disabled. Data exceeding the specified port size is broken into individual, port-sized, non-burst writes. For example, a 32-bit write to an 8-bit port takes four byte writes. 1 Enabled. Enables burst write of data larger than the specified port size, including 32-bit writes to 8- and 16-bit ports, 16-bit writes to 8-bit ports, and line writes to 8-, 16-, and 32-bit ports.
2–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

32.3.4 Chip Select port Multiplexing Control Register (FB_CSPMCR)

Controls the multiplexing of the FlexBus signals.

NOTE

A bus error occurs when you do any of the following:

- Write to a reserved address
- Write to a reserved field in this register, or
- Access this register using a size other than 32 bits.

Address: 4001_E000h base + 60h offset = 4001_E060h

Bit	31–28	27–24	23–20	19–16	15–12	11–0

15–12 GROUP5	FlexBus Signal Group 5 Multiplex control Controls the multiplexing of the FB_TA , FB_CS3 , and FB_BE_7_0 signals. **NOTE:** When GROUP5 is not 0000b, you must write 1b to the CSCR[AA] bit. Otherwise, the bus hangs during a transfer. 0000 FB_TA 0001 FB_CS3 . You must also write 1b to CSCR[AA]. 0010 FB_BE_7_0 . You must also write 1b to CSCR[AA]. Any other value Reserved
11–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

32.4 Functional description

32.4.1 Modes of operation

FlexBus supports the following modes of operation:

- Multiplexed 32-bit address and 32-bit data
- Multiplexed 32-bit address and 16-bit data (non-multiplexed 16-bit address and 16-bit data)
- Multiplexed 32-bit address and 8-bit data (non-multiplexed 24-bit address and 8-bit data)
- Non-multiplexed 32-bit address and 32-bit data busses

32.4.2 Address comparison

When a bus cycle is routed to FlexBus, FlexBus compares the transfer address to the base address (see CSAR[BA]) and base address mask (see CSMR[BAM]). This table describes how FlexBus decides to assert a chip-select and complete the bus cycle based on the address comparison.

When the transfer address	Then FlexBus
Matches one address register configuration	Asserts the appropriate chip-select, generating a FlexBus bus cycle as defined in the appropriate CSCR. If CSMR[WP] is set and a write access is performed, FlexBus terminates the internal bus cycle with a bus error, does not assert a chip-select, and does not perform an external bus cycle.
Does not match an address register configuration	Terminates the transfer with a bus error response, does not assert a chip-select, and does not perform a FlexBus cycle.
Matches more than one address register configuration	Terminates the transfer with a bus error response, does not assert a chip-select, and does not perform a FlexBus cycle.

32.4.3 Address driven on address bus

FlexBus always drives a 32-bit address on the FB_AD bus regardless of the external memory's or peripheral's address size.

32.4.4 Connecting address/data lines

The external device must connect its address and data lines as follows:

- Address lines
  - FB_AD from FB_AD0 upward
- Data lines
  - If CSCR[BLS] = 0, FB_AD from FB_AD31 downward
  - If CSCR[BLS] = 1, FB_AD from FB_AD0 upward

32.4.5 Bit ordering

No bit ordering is required when connecting address and data lines to the FB_AD bus. For example, a full 16-bit address/16-bit data device connects its addr15–addr0 to FB_AD16–FB_AD1 and data15–data0 to FB_AD31–FB_AD16. See Data-byte alignment and physical connections for a graphical connection.

32.4.6 Data transfer signals

Data transfers between FlexBus and the external memory or peripheral involve these signals:

- Address/data bus (FB_AD31–FB_AD0)
- Control signals ($\overline{\text{FB\_TS}}$/FB_ALE, $\overline{\text{FB\_TA}}$, $\overline{\text{FB\_CS}n}$, $\overline{\text{FB\_OE}}$, FB_R/$\overline{\text{W}}$, $\overline{\text{FB\_BE}n}$)
- Attribute signals ($\overline{\text{FB\_TBST}}$, FB_TSIZ1–FB_TSIZ0)

32.4.7 Signal transitions

These signals change on the rising edge of the FlexBus clock (FB_CLK):

- Address
- Write data
- $\overline{\text{FB\_TS}}$/FB_ALE
- $\overline{\text{FB\_CSn}}$
- All attribute signals

FlexBus latches the read data on the rising edge of the clock.

32.4.8 Data-byte alignment and physical connections

The device aligns data transfers in FlexBus byte lanes with the number of lanes depending on the data port width.

The following figure shows the byte lanes that external memory or peripheral connects to and the sequential transfers of a 32-bit transfer for the supported port sizes when byte lane shift is disabled. For example, an 8-bit memory connects to the single lane FB_AD31–FB_AD24 ($\overline{\text{FB\_BE\_31\_24}}$). A 32-bit transfer through this 8-bit port takes four transfers, starting with the LSB to the MSB. A 32-bit transfer through a 32-bit port requires one transfer on each four-byte lane.

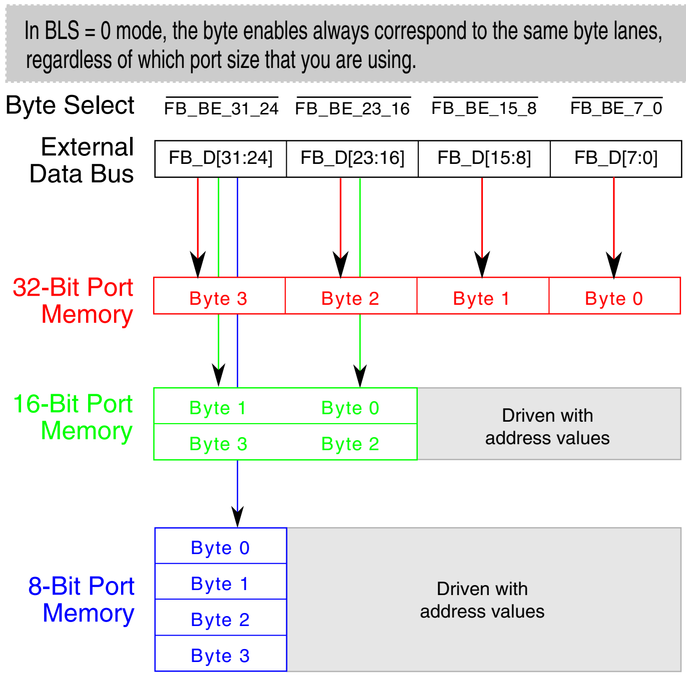

Figure 32-20. Connections for external memory port sizes (CSCRn[BLS] = 0)

The following figure shows the byte lanes that external memory or peripheral connects to and the sequential transfers of a 32-bit transfer for the supported port sizes when byte lane shift is enabled.

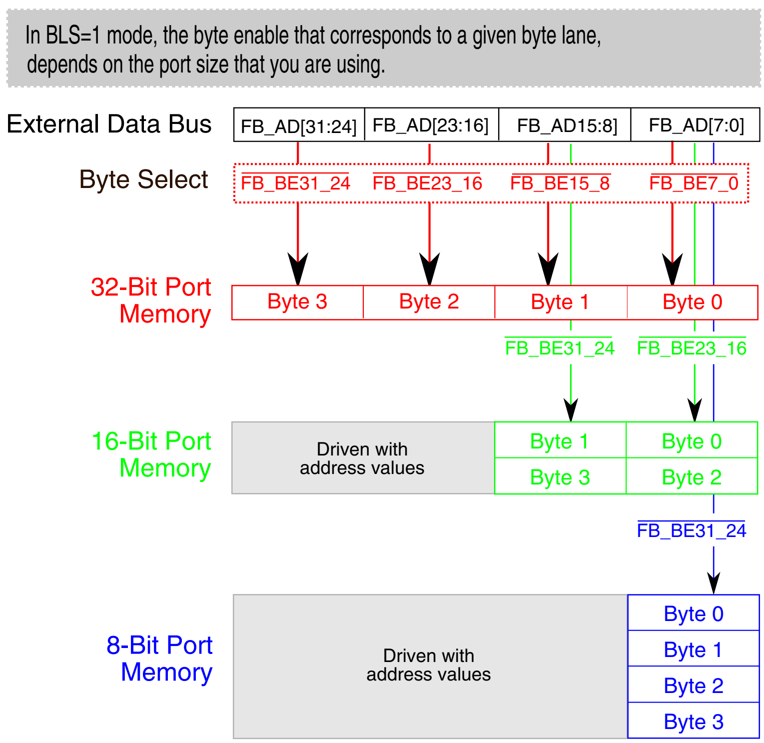

Figure 32-21. Connections for external memory port sizes (CSCRn[BLS] = 1)

32.4.9 Address/data bus multiplexing

FlexBus supports a single 32-bit wide multiplexed address and data bus (FB_AD31–FB_AD0). FlexBus always drives the full 32-bit address on the first clock of a bus cycle. During the data phase, the FB_AD31– FB_AD0 lines used for data are determined by the programmed port size and BLS setting for the corresponding chip-select. FlexBus continues to drive the address on any FB_AD31– FB_AD0 lines not used for data.

32.4.9.1 FlexBus multiplexed operating modes for CSCRn[BLS]=0

This table shows the supported combinations of address and data bus widths when CSCRn[BLS] is 0b.

<table>
<tr><th colspan="2" rowspan="2">Port size and phase</th><th colspan="4">FB_AD</th></tr>

</table>

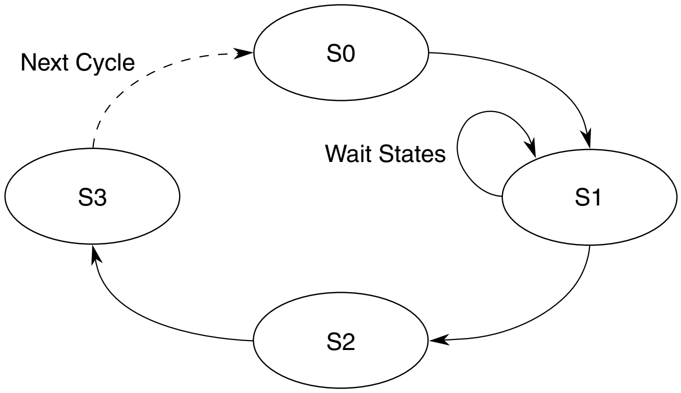
32.4.10 Data transfer states

Basic data transfers occur in four clocks or states. (See Figure 32-23 and Figure 32-25 for examples of basic data transfers.) The FlexBus state machine controls the data-transfer operation. This figure shows the state-transition diagram for basic read and write cycles.



The states are described in this table.

State	Cycle	Description
S0	All	The read or write cycle is initiated. On the rising clock edge, FlexBus: • Places a valid address on FB_ADn • Asserts FB_TS/FB_ALE • Drives FB_R/W high for a read and low for a write
S1	All	FlexBus: • Negates FB_TS/FB_ALE on the rising edge of FB_CLK • Asserts FB_CSn • Drives the data on FB_AD31– FB_ADX for writes • Tristates FB_AD31– FB_ADX for reads • Continues to drive the address on FB_AD pins that are unused for data If the external memory or perihperal asserts FB_TA, then the process moves to S2. If FB_TA is not asserted internally or externally, then S1 repeats.
	Read	The external memory or peripheral drives the data before the next rising edge of FB_CLK (the rising edge that begins S2) with FB_TA asserted.
S2	All	For internal termination, FlexBus negates FB_CSn and the transfer is complete. For external termination, the external memory or peripheral negates FB_TA, and FlexBus negates FB_CSn after the rising edge of FB_CLK at the end of S2.
	Read	FlexBus latches the data on the rising clock edge entering S2. The external memory or peripheral can stop driving the data after this edge or continue to drive the data until the end of S3 or through any additional address hold cycles.
S3	All	FlexBus invalidates the address, data, and FB_R/W on the rising edge of FB_CLK at the beginning of S3, terminating the transfer.

32.4.11 FlexBus Timing Examples

Note

The timing diagrams throughout this section use signal names that may not be included on your particular device. Ignore these extraneous signals.

Note

Throughout this section:

- FB_D[*X*] indicates a 32-, 16-, or 8-bit wide data bus
- FB_A[*Y*] indicates an address bus that can be 32, 24, or 16 bits wide.

32.4.11.1 Basic Read Bus Cycle

During a read cycle, the MCU receives data from memory or a peripheral device. The following figure shows a read cycle flowchart.

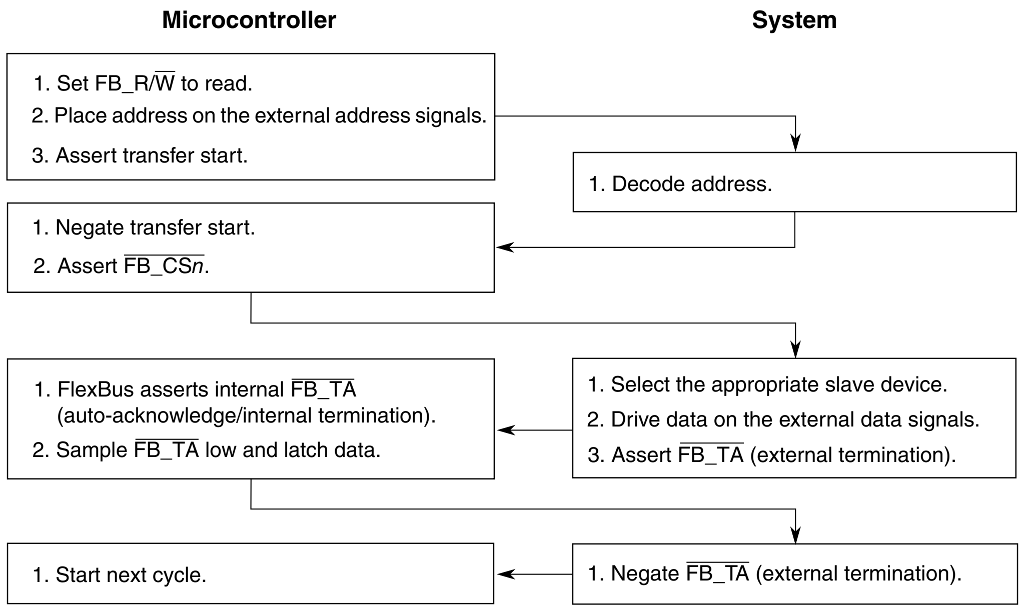


Figure 32-22. Read Cycle Flowchart

The read cycle timing diagram is shown in the following figure.

Note

FB_TA does not have to be driven by the external device for internally-terminated bus cycles.

Note

The processor drives the data lines during the first clock cycle of the transfer with the full 32-bit address. This may be ignored by standard connected devices using non-multiplexed address and data buses. However, some applications may find this feature beneficial.

The address and data busses are muxed between the FlexBus and another module. At the end of the read bus cycles the address signals are indeterminate.

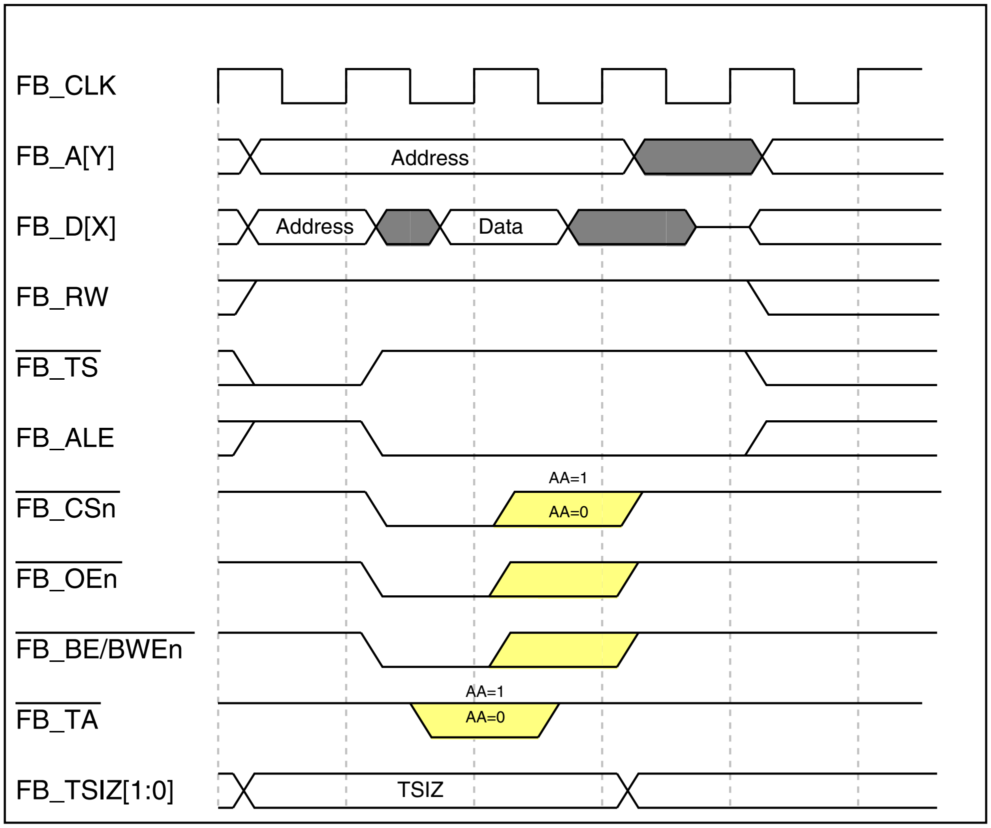

Figure 32-23. Basic Read-Bus Cycle

32.4.11.2 Basic Write Bus Cycle

During a write cycle, the device sends data to memory or to a peripheral device. The following figure shows the write cycle flowchart.

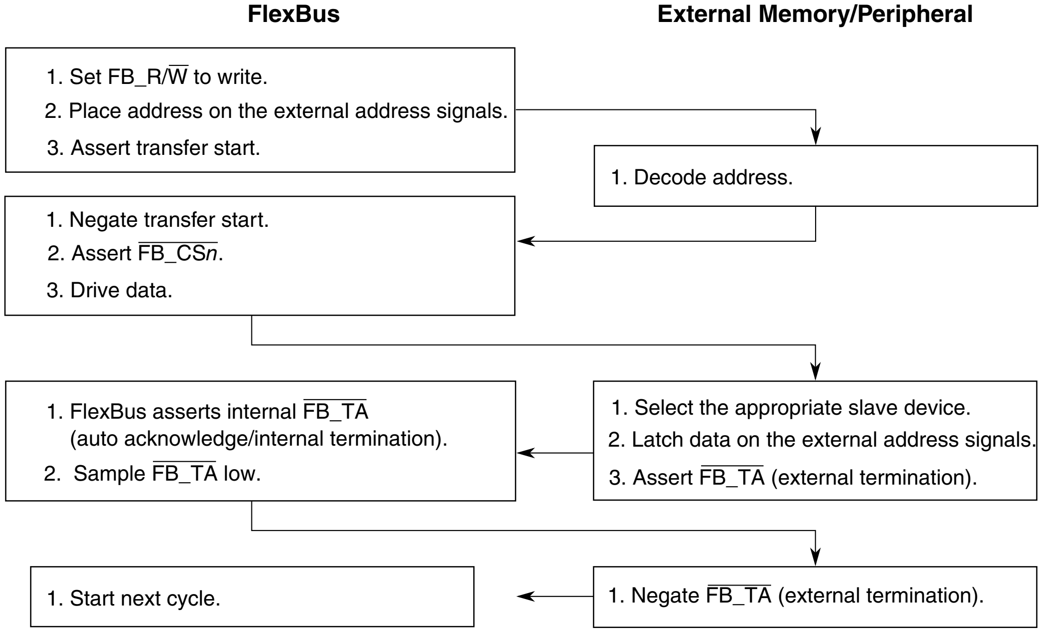

Figure 32-24. Write-Cycle Flowchart

The following figure shows the write cycle timing diagram.

Note

The address and data busses are muxed between the FlexBus and another module. At the end of the write bus cycles, the address signals are indeterminate.

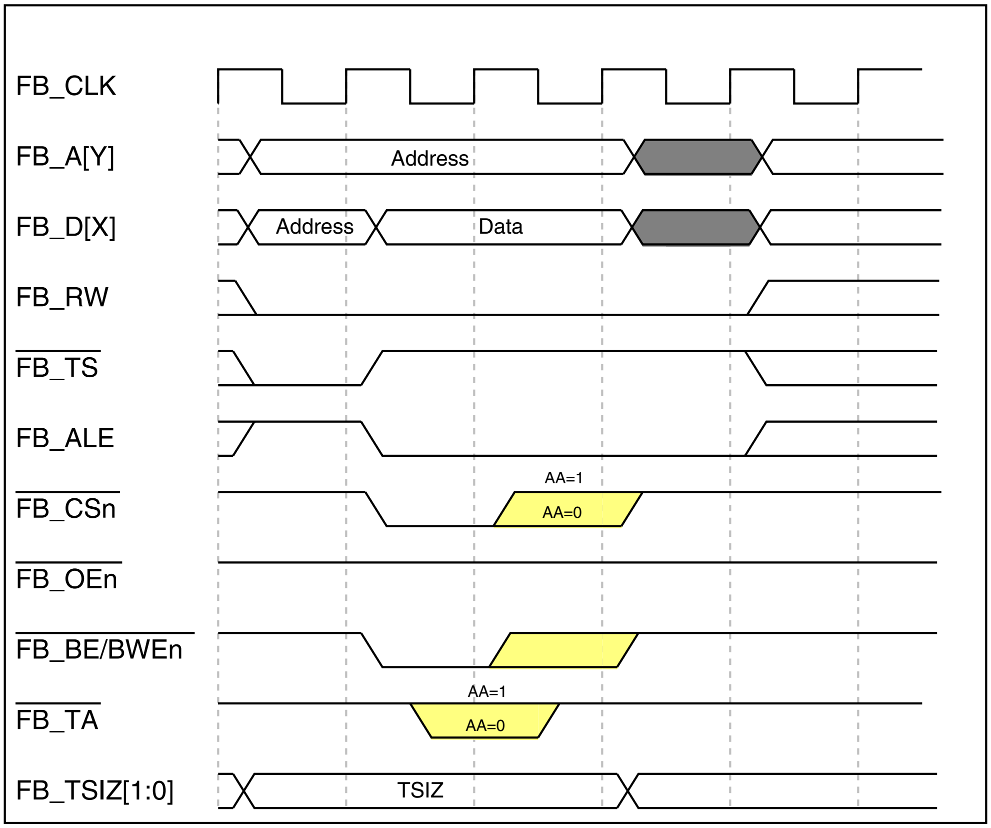

Figure 32-25. Basic Write-Bus Cycle

32.4.11.3 Bus Cycle Sizing

This section shows timing diagrams for various port size scenarios.

32.4.11.3.1 Bus Cycle Sizing—Byte Transfer, 8-bit Device, No Wait States

The following figure illustrates the basic byte read transfer to an 8-bit device with no wait states:

- The address is driven on the full FB_AD[31:8] bus in the first clock.
- The device tristates FB_AD[31:24] on the second clock and continues to drive address on FB_AD[23:0] throughout the bus cycle.
- The external device returns the read data on FB_AD[31:24] and may tristate the data line or continue driving the data one clock after FB_TA is sampled asserted.

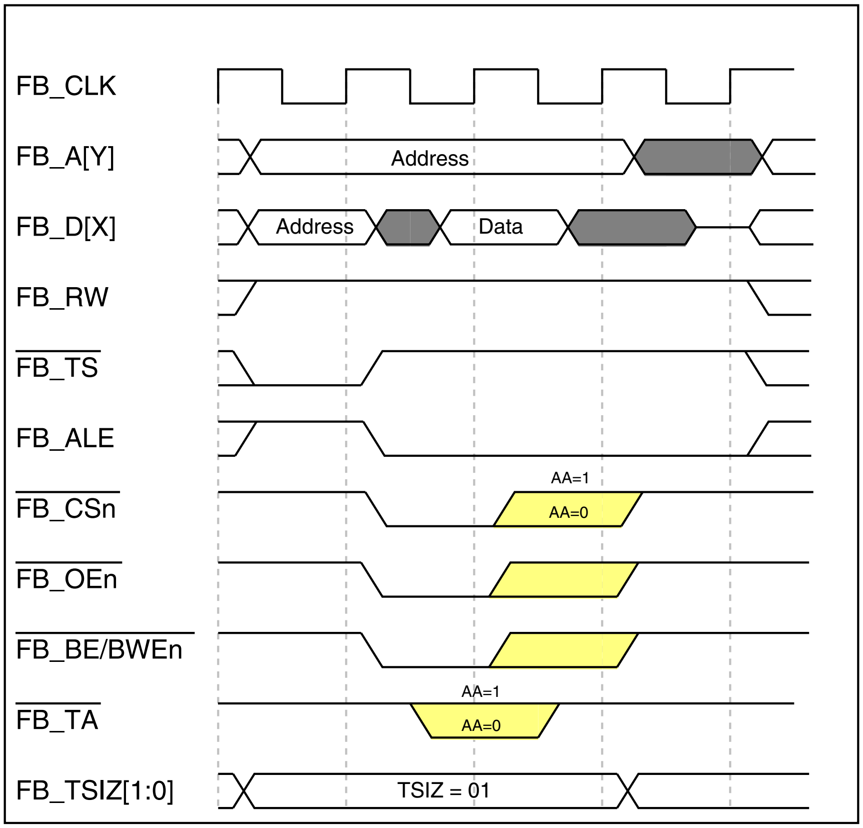

Figure 32-26. Single Byte-Read Transfer

The following figure shows the similar configuration for a write transfer. The data is driven from the second clock on FB_AD[31:24].

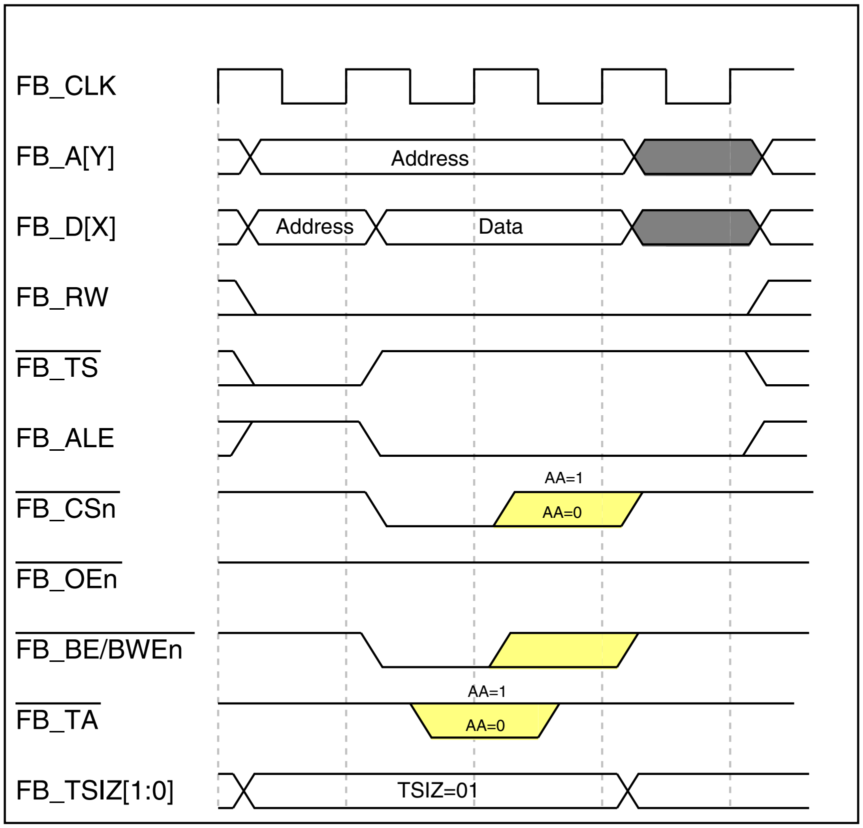

Figure 32-27. Single Byte-Write Transfer

32.4.11.3.2 Bus Cycle Sizing—Word Transfer, 16-bit Device, No Wait States

The following figure illustrates the basic word read transfer to a 16-bit device with no wait states.

- The address is driven on the full FB_AD[31:8] bus in the first clock.
- The device tristates FB_AD[31:16] on the second clock and continues to drive address on FB_AD[15:0] throughout the bus cycle.
- The external device returns the read data on FB_AD[31:16] and may tristate the data line or continue driving the data one clock after $\overline{\text{FB\_TA}}$ is sampled asserted.

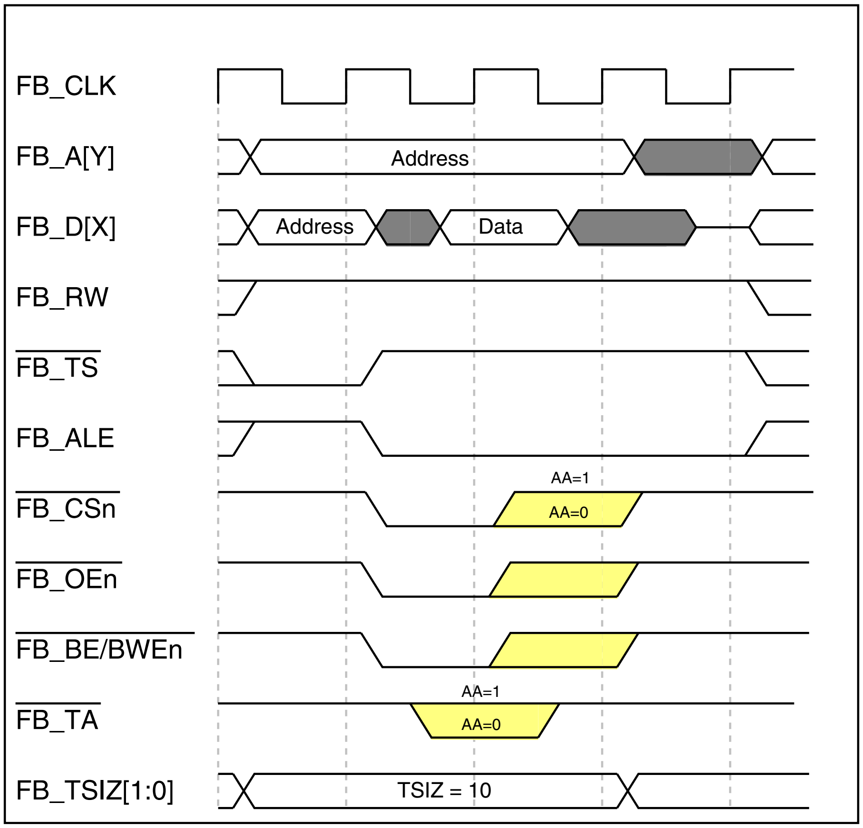

Figure 32-28. Single Word-Read Transfer

The following figure shows the similar configuration for a write transfer. The data is driven from the second clock on FB_AD[31:16].

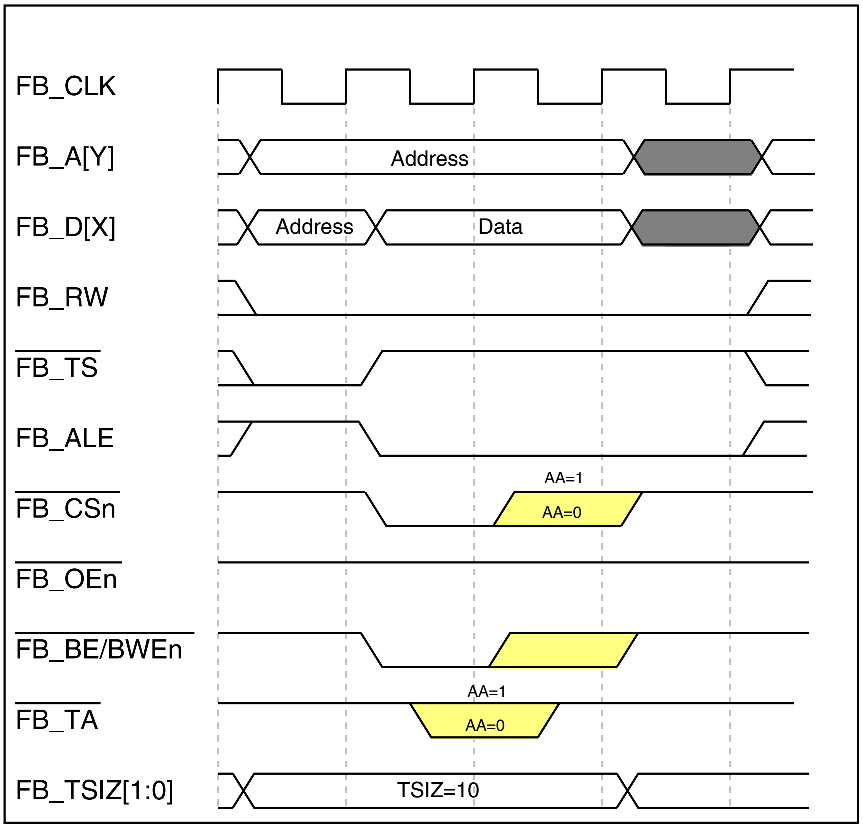

Figure 32-29. Single Word-Write Transfer

32.4.11.3.3 Bus Cycle Sizing—Longword Transfer, 32-bit Device, No Wait States

The following figure depicts a longword read from a 32-bit device.

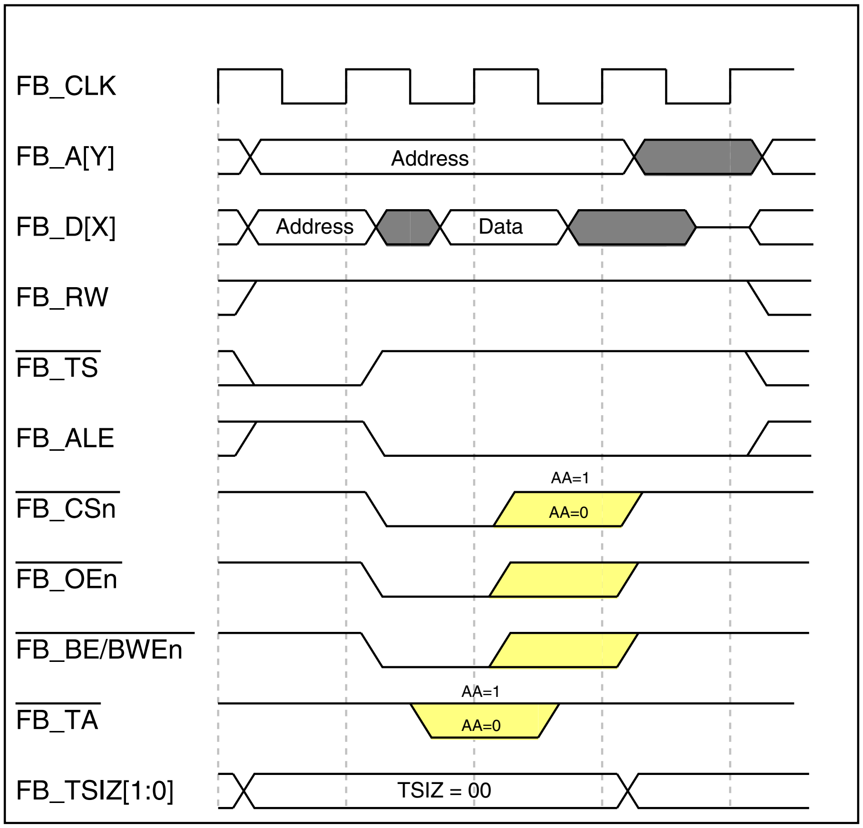

Figure 32-30. Longword-Read Transfer

The following figure illustrates the longword write to a 32-bit device.

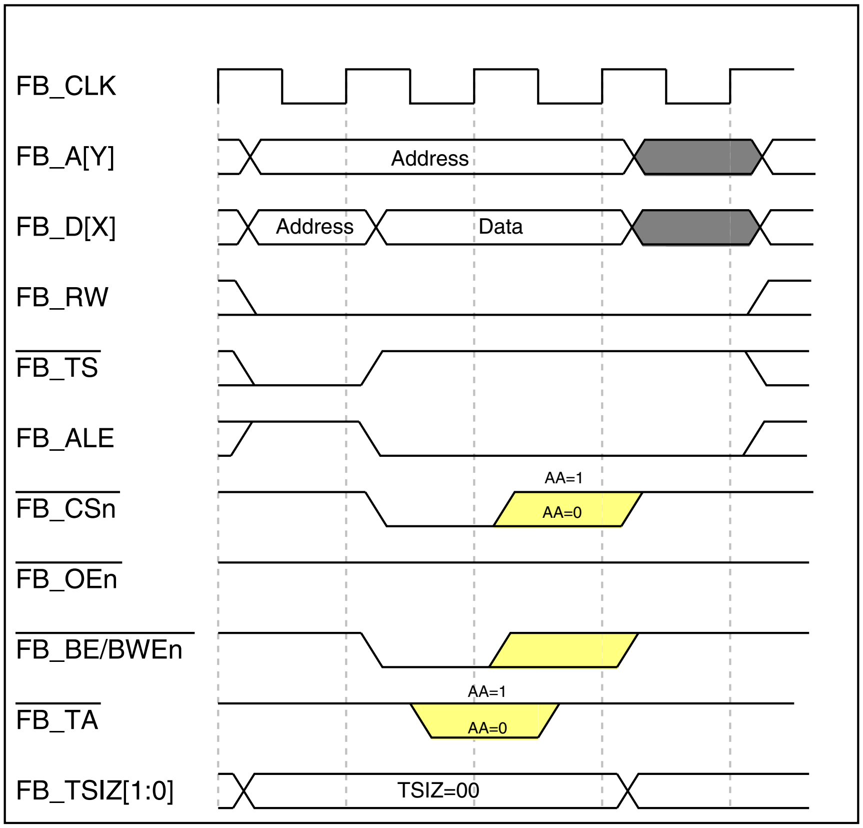

Figure 32-31. Longword-Write Transfer

32.4.11.4 Timing Variations

The FlexBus module has several features that can change the timing characteristics of a basic read- or write-bus cycle to provide additional address setup, address hold, and time for a device to provide or latch data.

32.4.11.4.1 Wait States

Wait states can be inserted before each beat of a transfer by programming the CSCR*n* registers. Wait states can give the peripheral or memory more time to return read data or sample write data.

The following figures show the basic read and write bus cycles (also shown in Figure 32-23 and Figure 32-28) with the default of no wait states respectively.

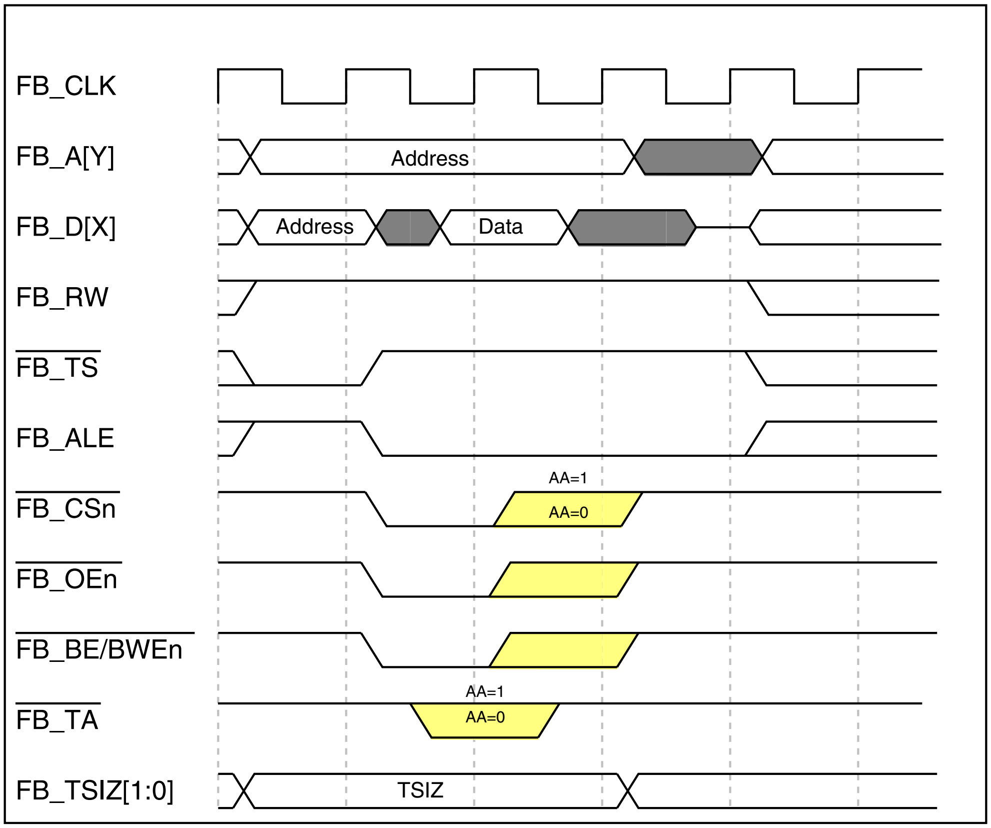

Figure 32-32. Basic Read-Bus Cycle (No Wait States)

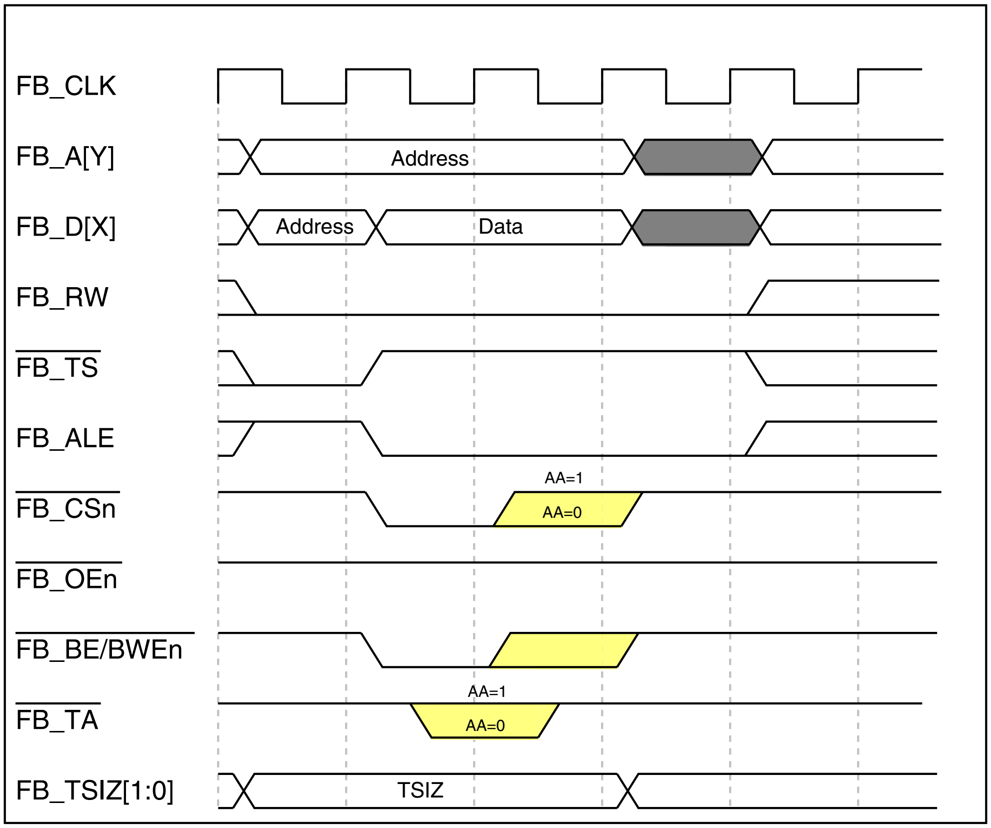

Figure 32-33. Basic Write-Bus Cycle (No Wait States)

If wait states are used, the S1 state repeats continuously until the chip-select auto-acknowledge unit asserts internal transfer acknowledge or the external $\overline{\text{FB\_TA}}$ is recognized as asserted. The following figures show a read and write cycle with one wait state respectively.

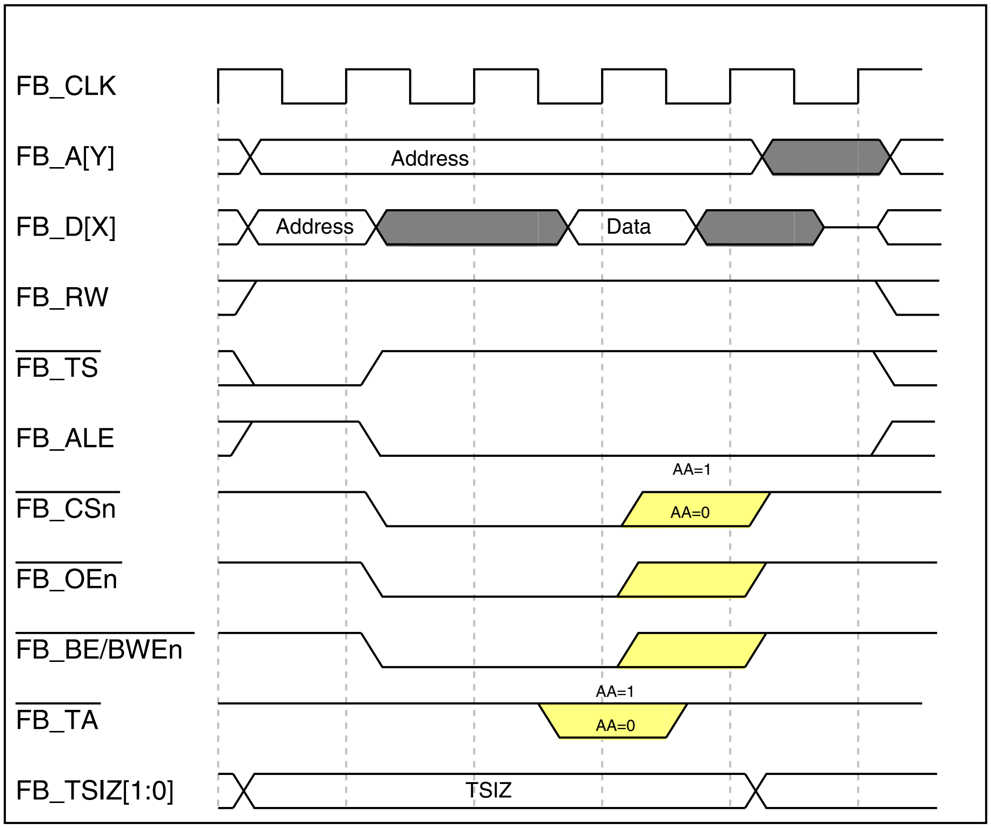

Figure 32-34. Read-Bus Cycle (One Wait State)

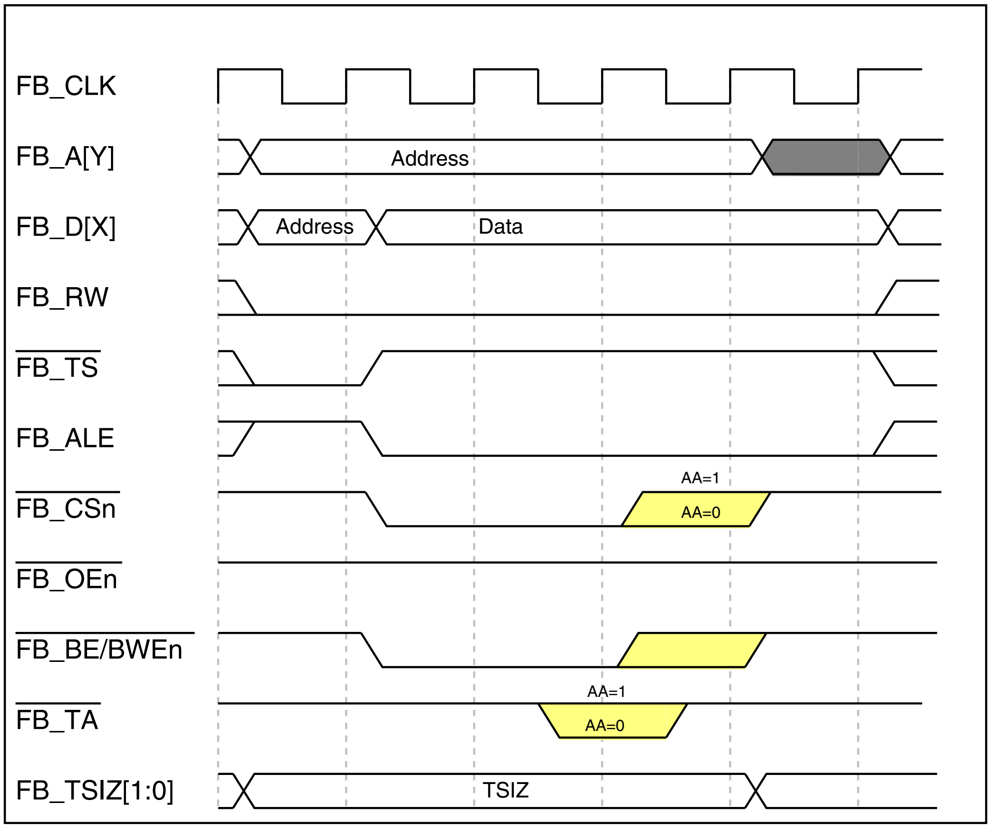

Figure 32-35. Write-Bus Cycle (One Wait State)

32.4.11.4.2 Address Setup and Hold

The timing of the assertion and negation of the chip selects, byte selects, and output enable can be programmed on a chip-select basis. Each chip-select can be programmed to assert one to four clocks after transfer start/address-latch enable (FB_TS/FB_ALE) is asserted. The following figures show read- and write-bus cycles with two clocks of address setup respectively.

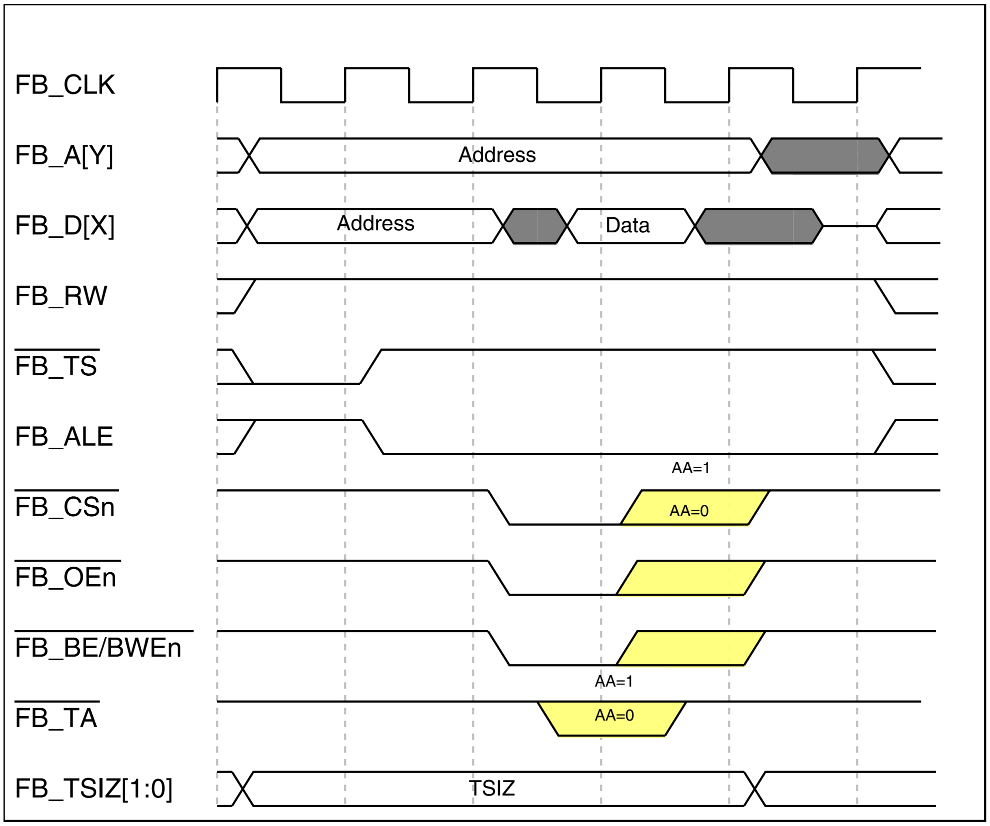

Figure 32-36. Read-Bus Cycle with Two-Clock Address Setup (No Wait States)

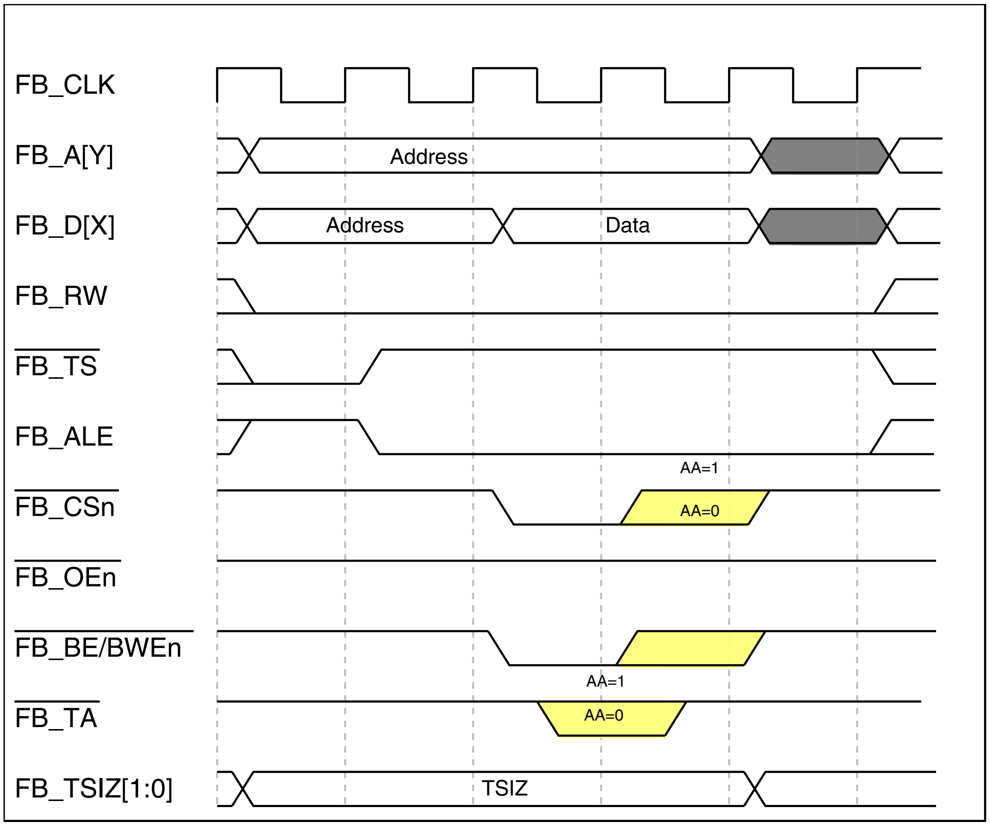

Figure 32-37. Write-Bus Cycle with Two Clock Address Setup (No Wait States)

In addition to address setup, a programmable address hold option for each chip select exists. Address and attributes can be held one to four clocks after chip-select, byte-selects, and output-enable negate. The following figures show read and write bus cycles with two clocks of address hold respectively.

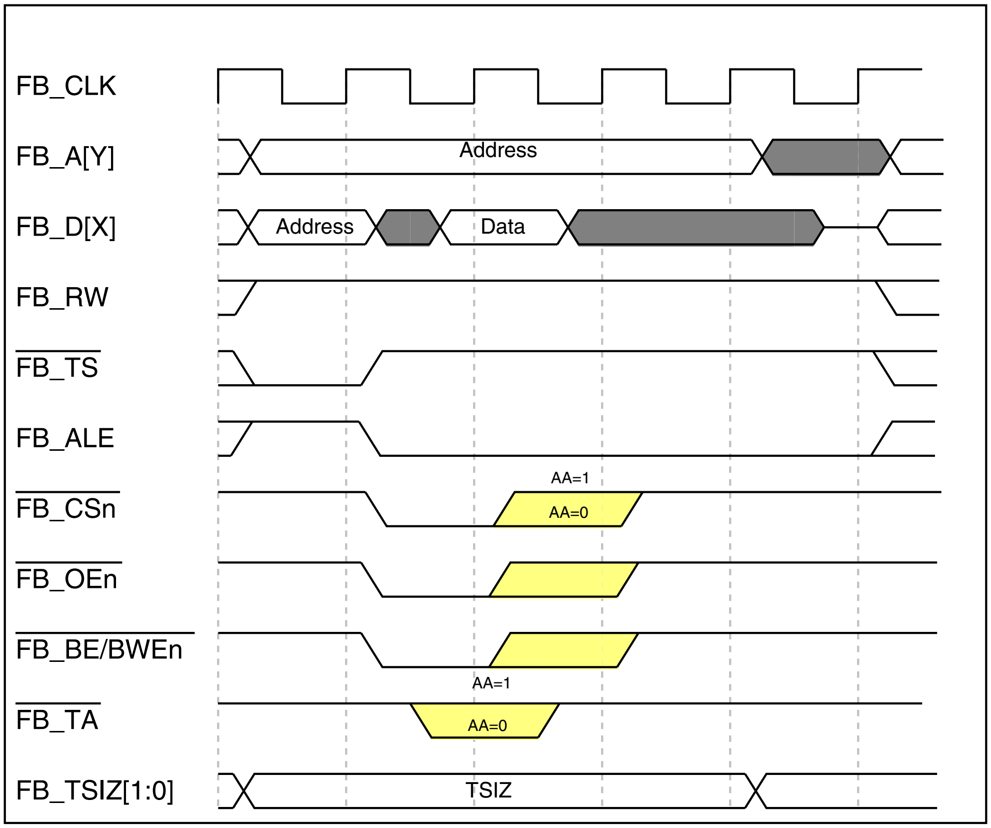

Figure 32-38. Read Cycle with Two-Clock Address Hold (No Wait States)

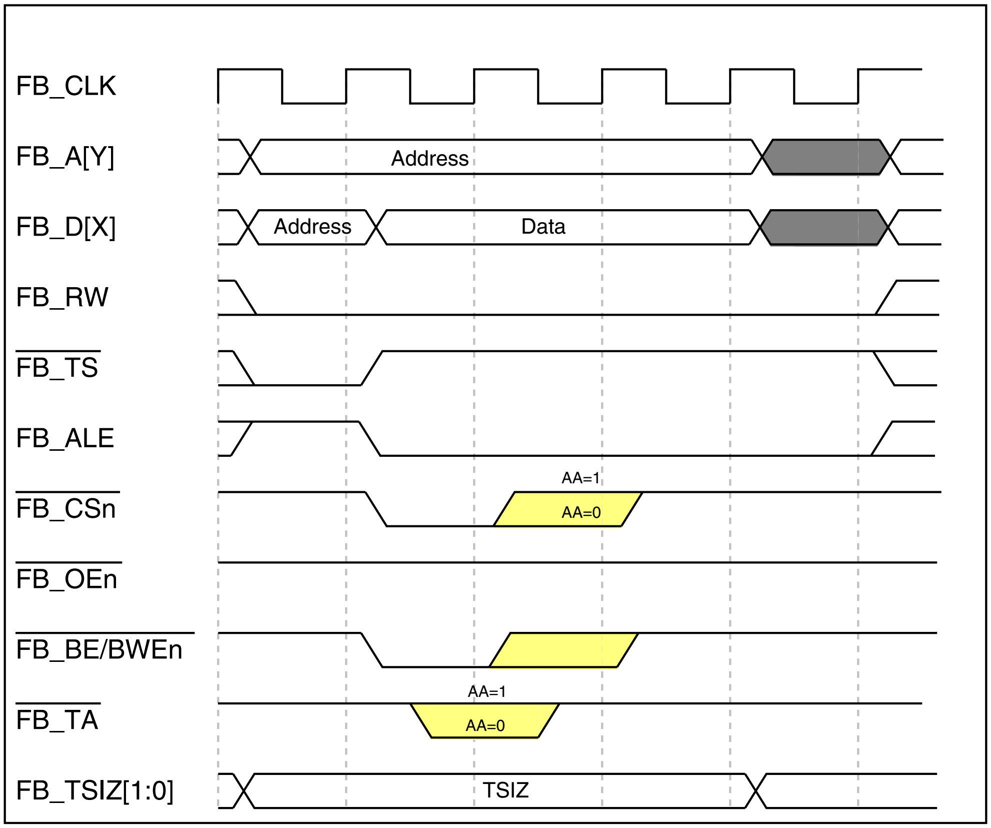

Figure 32-39. Write Cycle with Two-Clock Address Hold (No Wait States)

The following figure shows a bus cycle using address setup, wait states, and address hold.

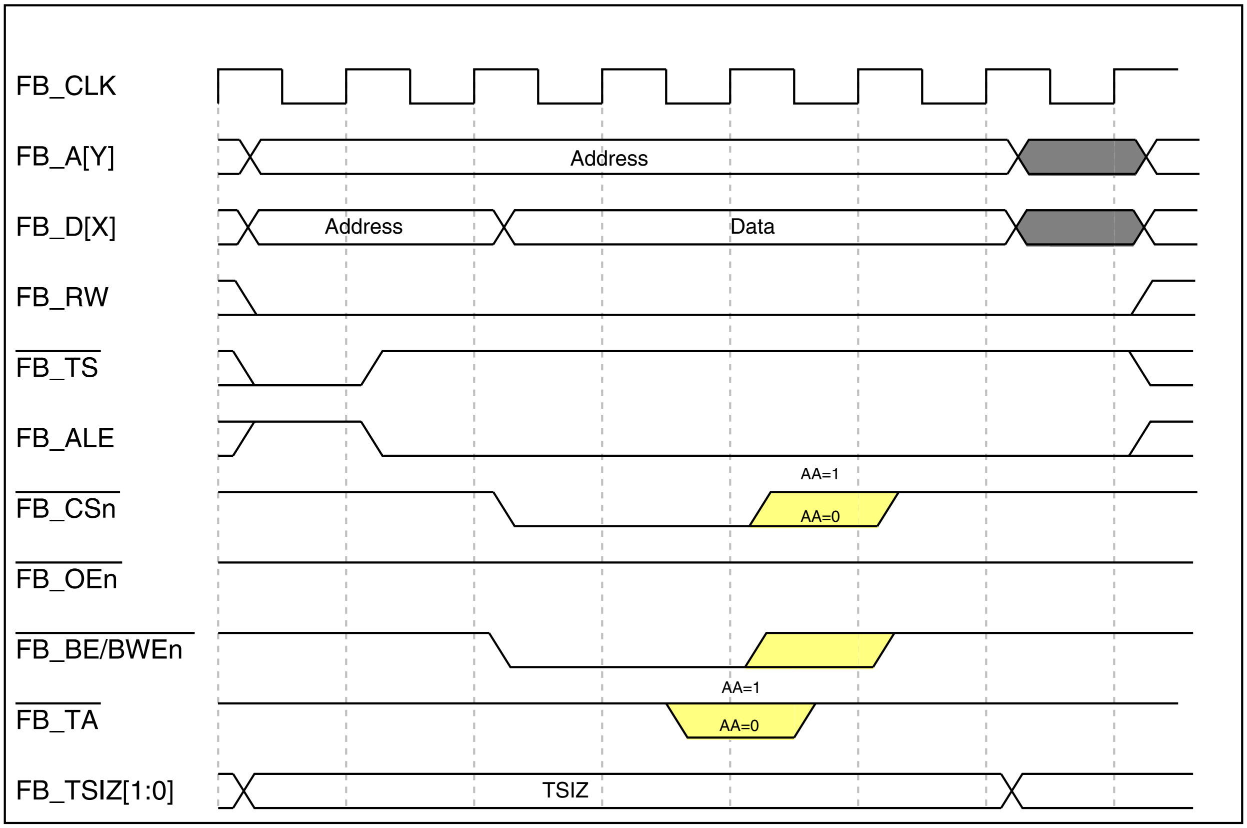

Figure 32-40. Write Cycle with Two-Clock Address Setup and Two-Clock Hold (One Wait State)

32.4.12 Burst cycles

The chip can be programmed to initiate burst cycles if its transfer size exceeds the port size of the selected destination. The initiation of a burst cycle is encoded on the transfer size pins (FB_TSIZ[1:0]). For burst transfers to smaller port sizes, FB_TSIZ[1:0] indicates the size of the entire transfer. For example, with bursting enabled, a 16-bit transfer to an 8-bit port takes two beats (two byte-sized transfers), for which FB_TSIZ[1:0] equals 10b throughout. A 32-bit transfer to an 8-bit port takes four beats (four byte-sized transfers), for which FB_TSIZ[1:0] equals 00b throughout.

32.4.12.1 Enabling and inhibiting burst

The CSCRn registers enable bursting for reads, writes, or both.

Memory spaces can be declared burst-inhibited for reads and writes by writing 0b to the appropriate CSCRn[BSTR] and CSCRn[BSTW] fields.

32.4.12.2 Transfer size and port size translation

With bursting disabled, any transfer larger than the port size breaks into multiple individual transfers (e.g. <Addr><Data><Addr+1><Data><Addr+2><Data>). With bursting enabled, any transfer larger than the port size results in a burst cycle of multiple beats (e.g. <Addr><Data><Data><Data>). The following table shows the result of such transfer translations.

Port size PS[1:0]	Transfer size FB_TSIZ[1:0]	Burst-inhibited: Number of transfers Burst enabled: Number of beats
01b (8 bit)	10b (16 bits)	2
	00b (32 bits)	4
	11b (16 bytes)	16
1Xb (16 bit)	00b (32 bits)	2
	11b (16 bytes)	8
00b (32 bit)	11b (line)	4

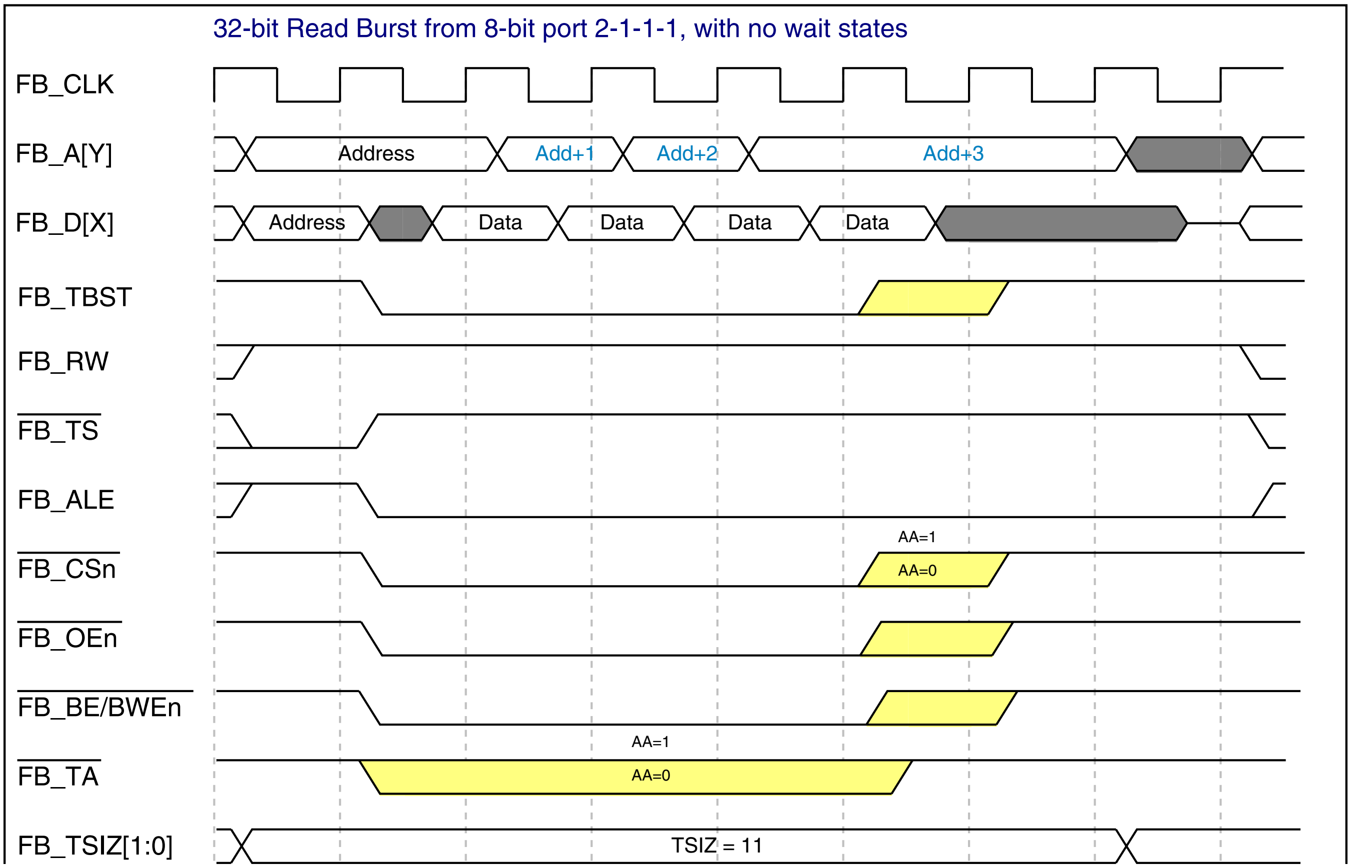
The FlexBus can support X-1-1-1 burst cycles to maximize system performance, where X is the primary number of wait states (max 63). Delaying termination of the cycle can add wait states. If internal termination is used, different wait state counters can be used for the first access and the following beats.

32.4.12.3 32-bit-Read burst from 8-Bit port 2-1-1-1 (no wait states)

The following figure shows a 32-bit read to an 8-bit external chip programmed for burst enable. The transfer results in a 4-beat burst and the data is driven on FB_AD[31:24]. The transfer size is driven at 32-bit (00b) throughout the bus cycle.

Note

> In non-multiplexed address/data mode, the address on FB_A increments only during internally-terminated burst cycles. The first address is driven throughout the entire burst for externally-terminated cycles.
>
> In multiplexed address/data mode, the address is driven on FB_AD only during the first cycle for all terminated cycles.

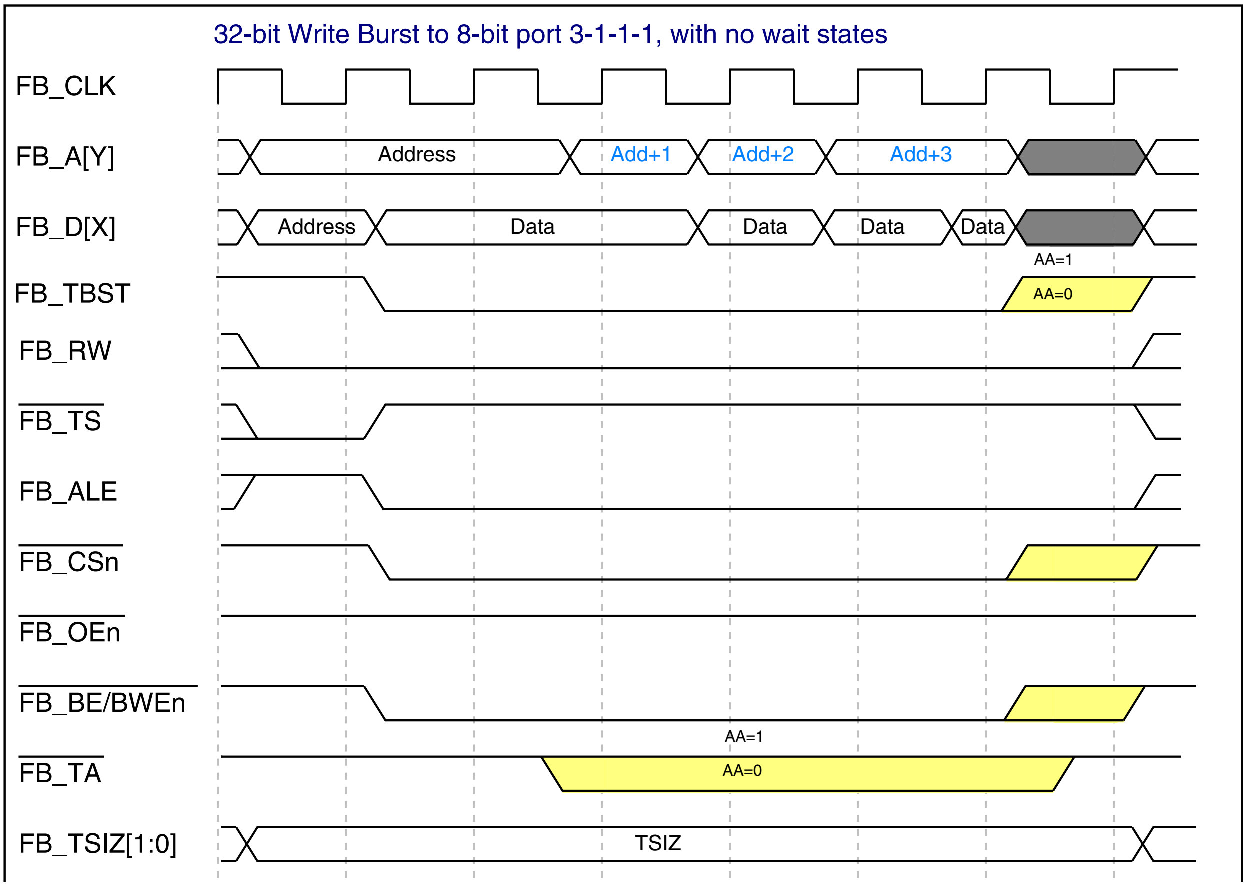


32.4.12.4 32-bit-Write burst to 8-Bit port 3-1-1-1 (no wait states)

The following figure shows a 32-bit write to an 8-bit external chip with burst enabled. The transfer results in a 4-beat burst and the data is driven on FB_AD[31:24]. The transfer size is driven at 32-bit (00b) throughout the bus cycle.

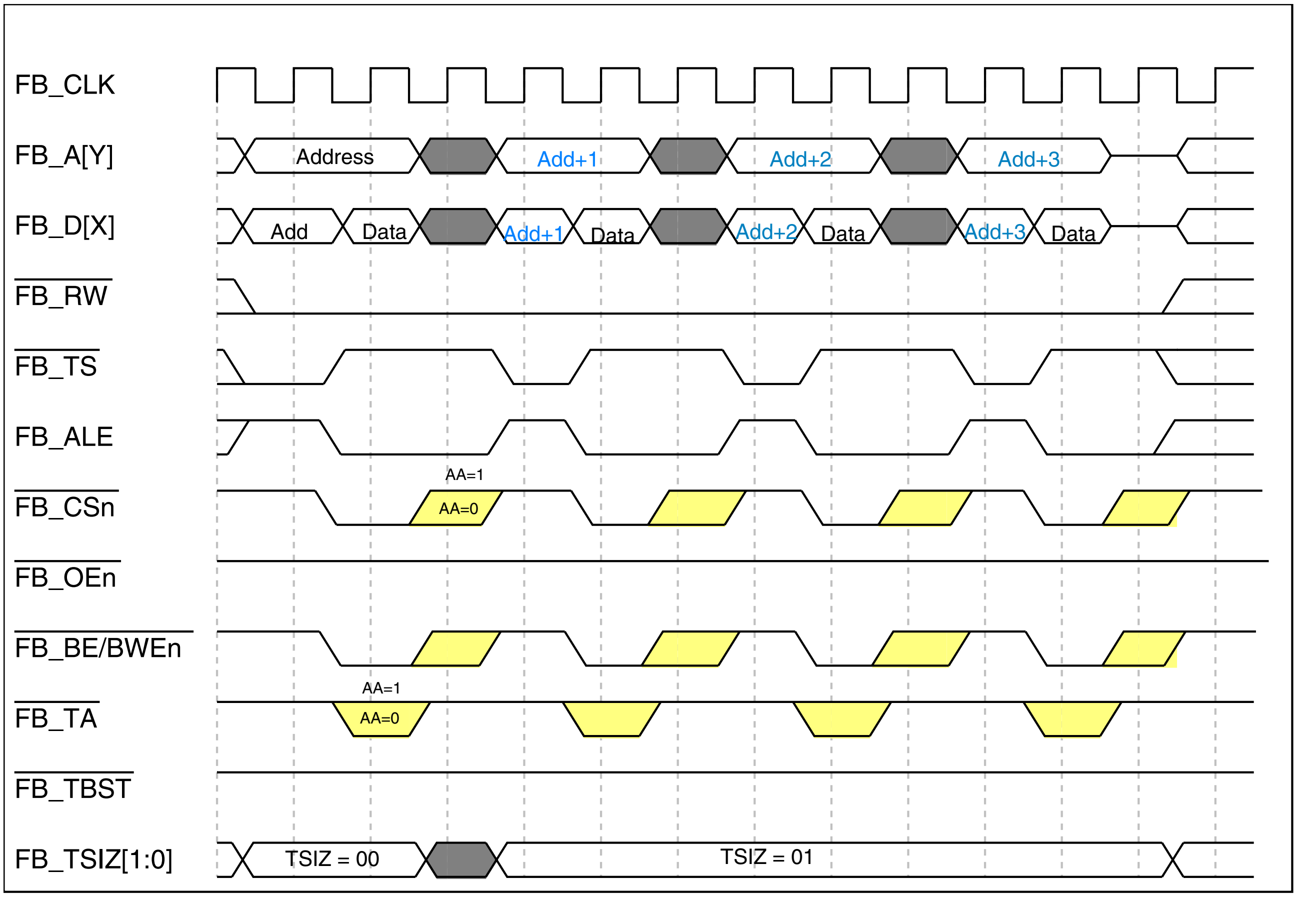
Note

The first beat of any write burst cycle has at least one wait state. If the bus cycle is programmed for zero wait states (CSCRn[WS] = 0b), one wait state is added. Otherwise, the programmed number of wait states are used.



32.4.12.5 32-bit-write burst-inhibited to 8-bit port (no wait states)

The following figure shows a 32-bit write to an 8-bit device with burst inhibited. The transfer results in four individual transfers. The transfer size is driven at 32-bit (00b) during the first transfer and at byte (01b) during the next three transfers.

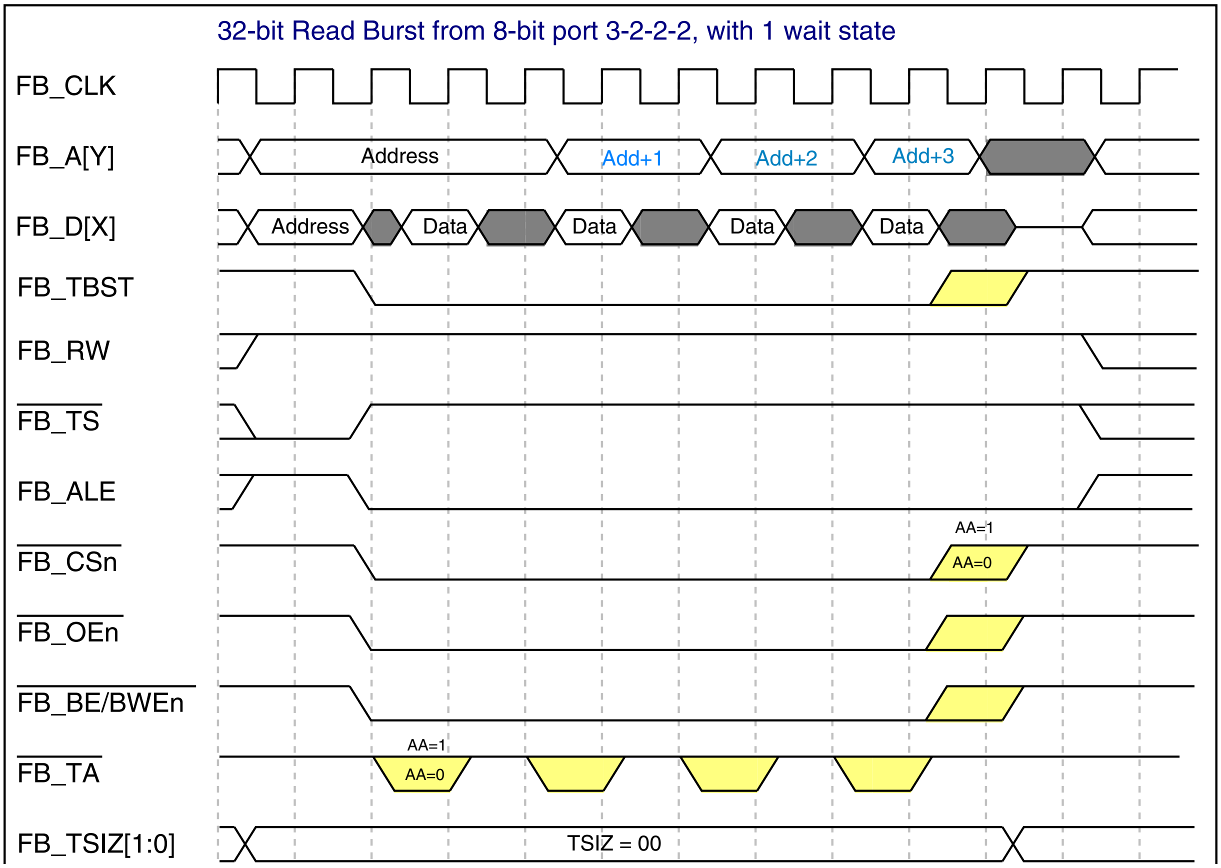


32.4.12.6 32-bit-read burst from 8-bit port 3-2-2-2 (one wait state)

The following figure illustrates another read burst transfer, but in this case a wait state is added between individual beats.

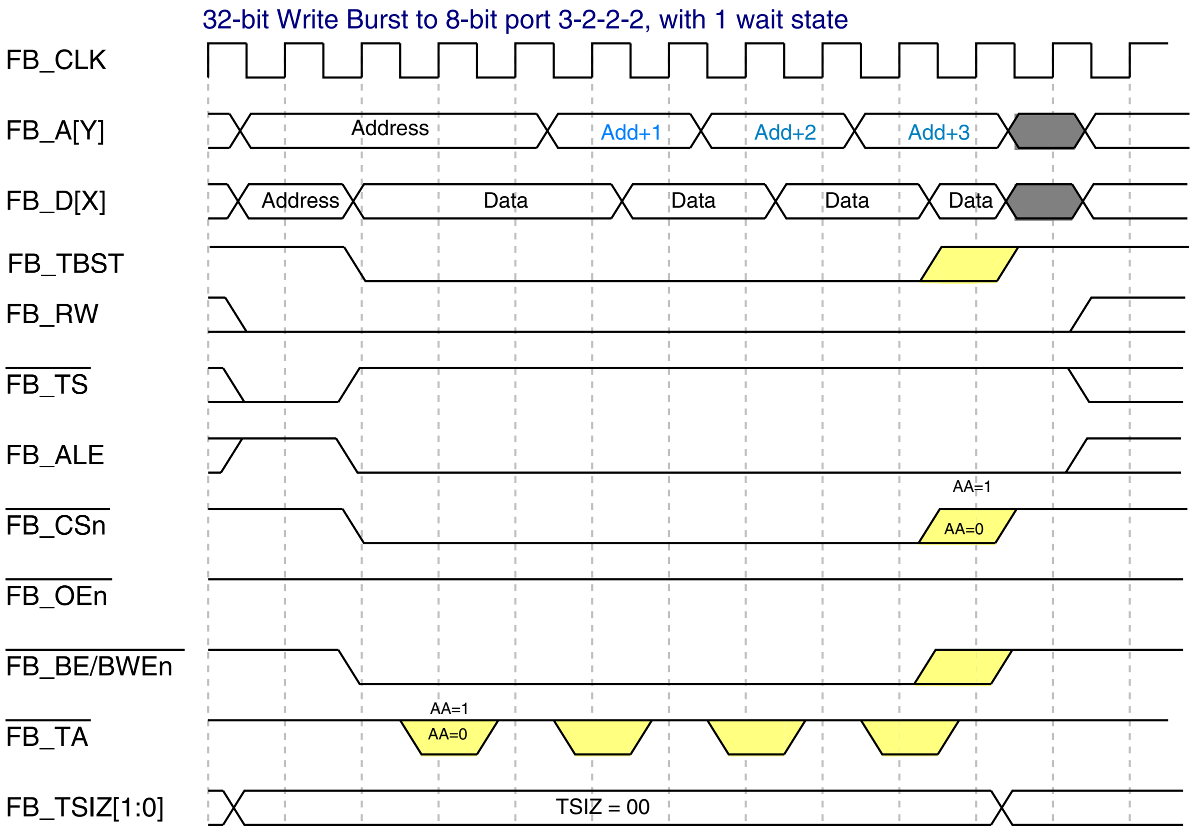
Note

CSCRn[WS] determines the number of wait states in the first beat. However, for subsequent beats, the CSCRn[WS] (or CSCRn[SWS] if CSCRn[SWSEN] = 1b) determines the number of wait states.



32.4.12.7 32-bit-write burst to 8-bit port 3-2-2-2 (one wait state)

The following figure illustrates a write burst transfer with one wait state.



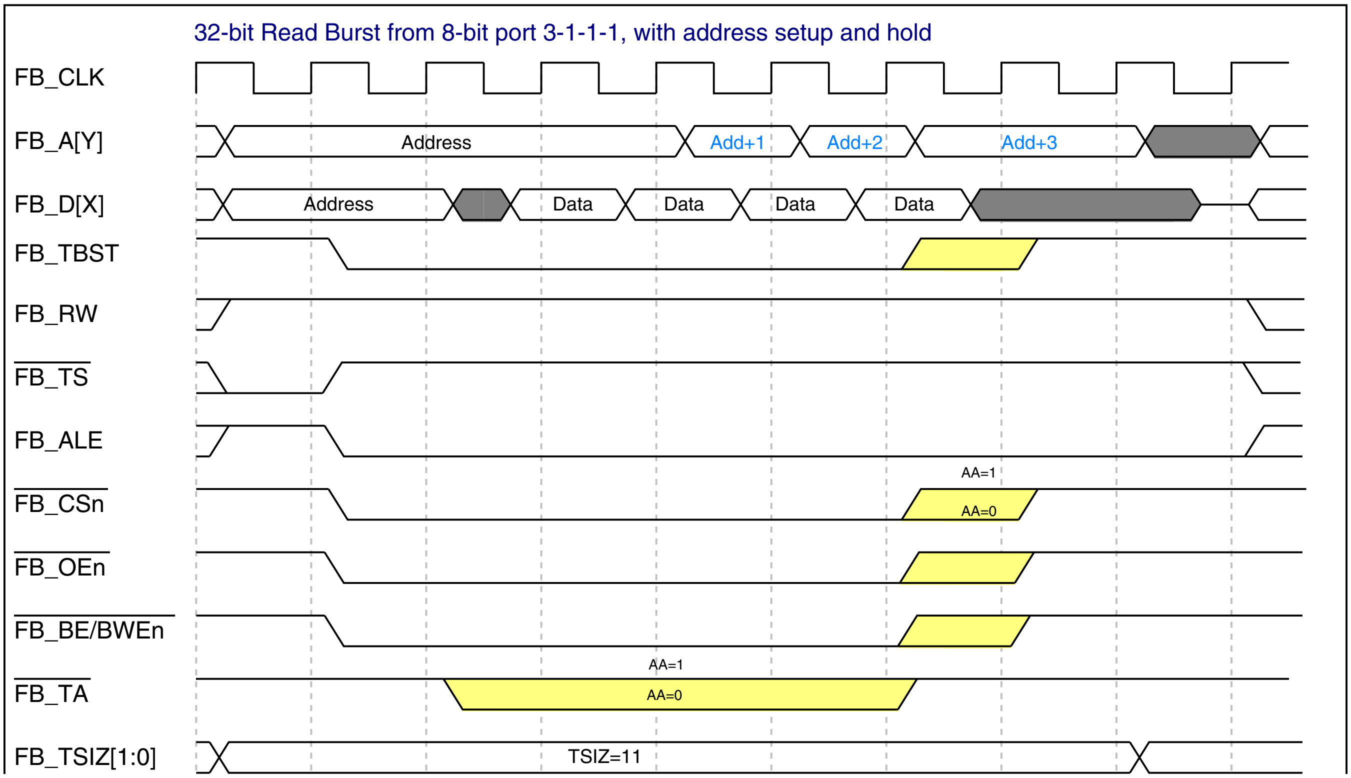
32.4.12.8 32-bit-read burst from 8-bit port 3-1-1-1 (address setup and hold)

If address setup and hold are used, only the first and last beat of the burst cycle are affected. The following figure shows a read cycle with one clock of address setup and address hold.

Note

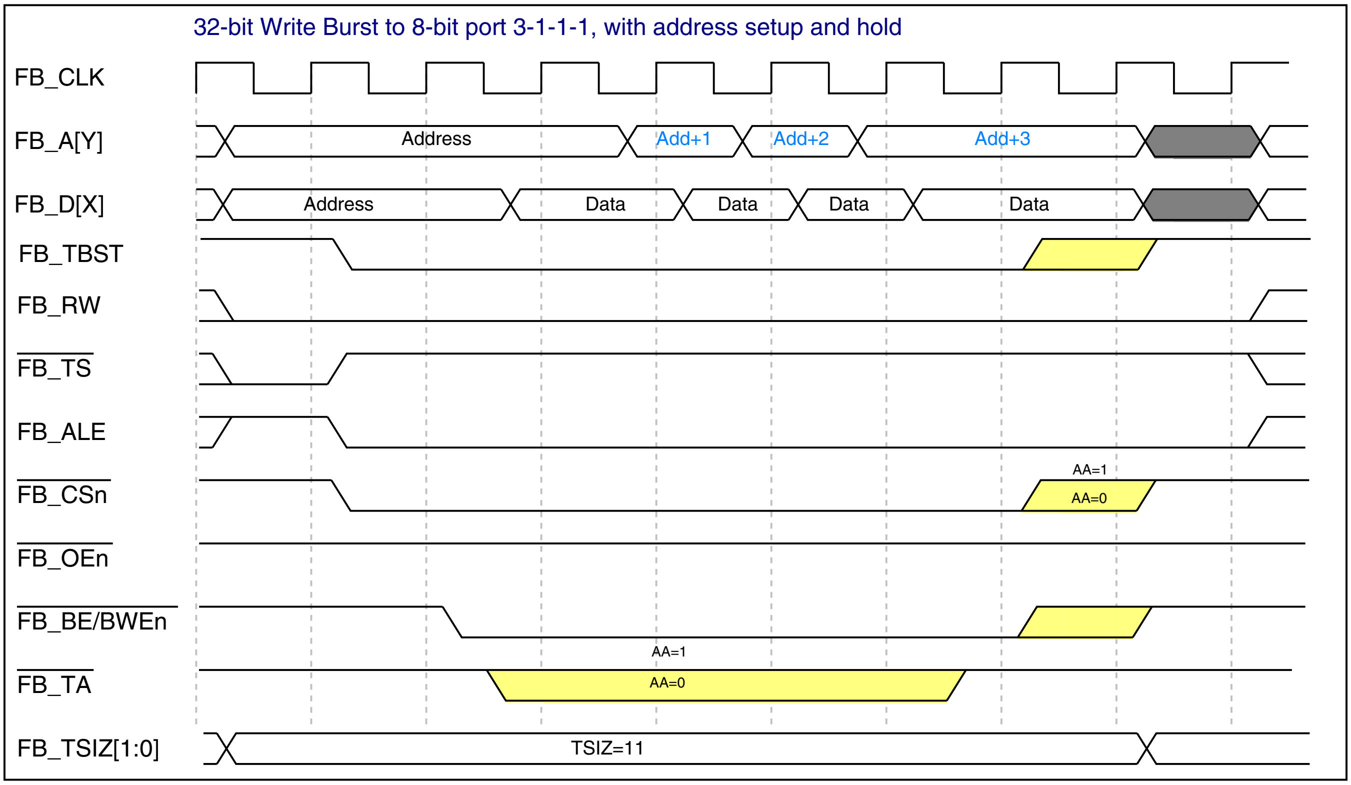
In non-multiplexed address/data mode, the address on FB_A increments only during internally-terminated burst cycles (CSCRn[AA] = 1b). The attached device must be able to account for this, or a wait state must be added. The first address is driven throughout the entire burst for externally-terminated cycles.

In multiplexed address/data mode, the address is driven on FB_AD only during the first cycle for internally- and externally-terminated cycles.



32.4.12.9 32-bit-write burst to 8-bit port 3-1-1-1 (address setup and hold)

The following figure shows a write cycle with one clock of address setup and address hold.



32.4.13 Extended Transfer Start/Address Latch Enable

The FB_TS/FB_ALE signal indicates that a bus transaction has begun and the address and attributes are valid. By default, the FB_TS/FB_ALE signal asserts for a single bus clock cycle. When CSCR*n*[EXTS] is set, the FB_TS/FB_ALE signal asserts and remain asserted until the first positive clock edge after FB_CS*n* asserts. See the following figure.

NOTE

When EXTS is set, CSCR*n*[WS] must be programmed to have at least one primary wait state.

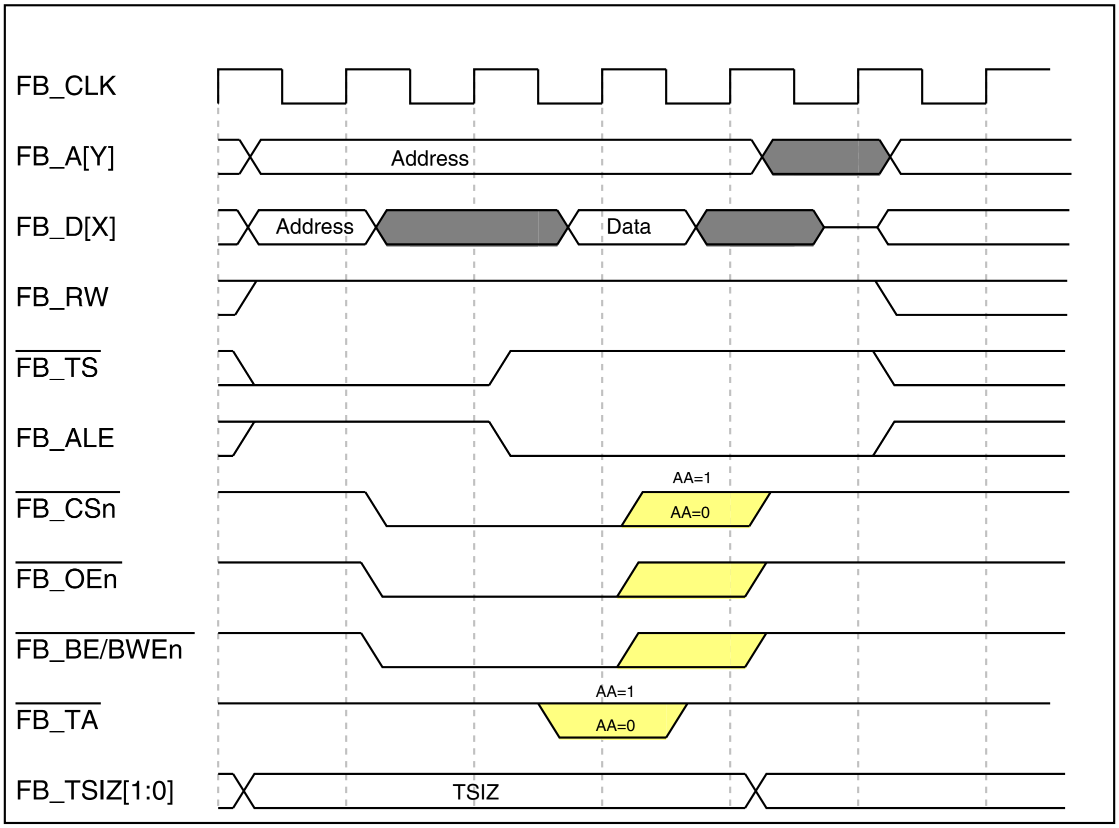


Figure 32-41. Read-Bus Cycle with CSCR*n*[EXTS] = 1 (One Wait State)

32.4.14 Bus errors

These types of accesses cause a transfer to terminate with a bus error:

- A write to a write-protected address range
- An access whose address is not in a range covered by a chip-select
- An access whose address is in a range covered by more than one chip-selects
- A write to a reserved address in the memory map
- A write to a reserved field in the CSPMCR
- Any FlexBus accesses when FlexBus is secure

If the auto-acknowledge feature is disabled (CSCR[AA] is 0) for an address that generates an error, the transfer can be terminated by asserting FB_TA. If the processor must manage a bus error differently, asserting an interrupt to the core along with FB_TA when the bus error occurs can invoke an interrupt handler.

The device can hang if FlexBus is configured for external termination and the CSPMCR is not configured for FB_TA.

32.5 Initialization/Application Information

32.5.1 Initializing a chip-select

To initialize a chip-select:

1. Write to the associated CSAR.
2. Write to the associated CSCR.
3. Write to the associated CSMR, including writing 1b to the Valid field (CSMRn[V]).

32.5.2 Reconfiguring a chip-select

To reconfigure a previously-used chip-select:

1. Invalidate the chip-select by writing 0b to the associated CSMR's Valid field (CSMRn[V]).
2. Write to the associated CSAR.
3. Write to the associated CSCR.
4. Write to the associated CSMR, including writing 1b to the Valid field (CSMRn[V]).

Chapter 33
Cyclic Redundancy Check (CRC)

33.1 Introduction

NOTE

For the chip-specific implementation details of this module's instances see the chip configuration information.

The cyclic redundancy check (CRC) module generates 16/32-bit CRC code for error detection.

The CRC module provides a programmable polynomial, WAS, and other parameters required to implement a 16-bit or 32-bit CRC standard.

The 16/32-bit code is calculated for 32 bits of data at a time.

33.1.1 Features

Features of the CRC module include:

- Hardware CRC generator circuit using a 16-bit or 32-bit programmable shift register
- Programmable initial seed value and polynomial
- Option for inversion of final CRC result
- 32-bit CPU register programming interface

33.1.2 Block diagram

The following is a block diagram of the CRC.

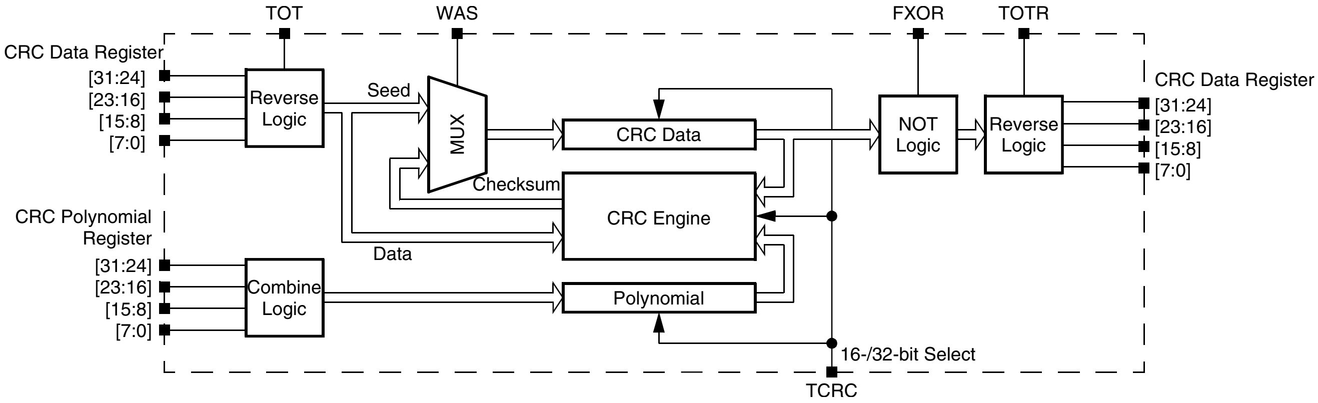

Figure 33-1. Programmable cyclic redundancy check (CRC) block diagram

33.1.3 Modes of operation

Various MCU modes affect the CRC module's functionality.

33.1.3.1 Run mode

This is the basic mode of operation.

33.1.3.2 Low-power modes (Wait or Stop)

Any CRC calculation in progress stops when the MCU enters a low-power mode that disables the module clock. It resumes after the clock is enabled or via the system reset for exiting the low-power mode. Clock gating for this module is dependent on the MCU.

33.2 Memory map and register descriptions

CRC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4003_3000	CRC Data register (CRC_DATA)	32	R/W	FFFF_FFFFh	33.2.1/1381
4003_3004	CRC Polynomial register (CRC_GPOLY)	32	R/W	0000_1021h	33.2.2/1382
4003_3008	CRC Control register (CRC_CTRL)	32	R/W	0000_0000h	33.2.3/1382

33.2.1 CRC Data register (CRC_DATA)

The CRC Data register contains the value of the seed, data, and checksum. When CTRL[WAS] is set, any write to the data register is regarded as the seed value. When CTRL[WAS] is cleared, any write to the data register is regarded as data for general CRC computation.

In 16-bit CRC mode, the HU and HL fields are not used for programming the seed value, and reads of these fields return an indeterminate value. In 32-bit CRC mode, all fields are used for programming the seed value.

When programming data values, the values can be written 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous; with MSB of data value written first.

After all data values are written, the CRC result can be read from this data register. In 16-bit CRC mode, the CRC result is available in the LU and LL fields. In 32-bit CRC mode, all fields contain the result. Reads of this register at any time return the intermediate CRC value, provided the CRC module is configured.

Address: 4003_3000h base + 0h offset = 4003_3000h

Bit	31–24	23–16	15–8	7–0
R/W	HU	HL	LU	LL
Reset	1 1 1 1 1 1 1 1	1 1 1 1 1 1 1 1	1 1 1 1 1 1 1 1	1 1 1 1 1 1 1 1

CRC_DATA field descriptions

Field	Description
31–24 HU	CRC High Upper Byte In 16-bit CRC mode (CTRL[TCRC] is 0), this field is not used for programming a seed value. In 32-bit CRC mode (CTRL[TCRC] is 1), values written to this field are part of the seed value when CTRL[WAS] is 1. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes.
23–16 HL	CRC High Lower Byte In 16-bit CRC mode (CTRL[TCRC] is 0), this field is not used for programming a seed value. In 32-bit CRC mode (CTRL[TCRC] is 1), values written to this field are part of the seed value when CTRL[WAS] is 1. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation in both 16-bit and 32-bit CRC modes.
15–8 LU	CRC Low Upper Byte When CTRL[WAS] is 1, values written to this field are part of the seed value. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation.
7–0 LL	CRC Low Lower Byte When CTRL[WAS] is 1, values written to this field are part of the seed value. When CTRL[WAS] is 0, data written to this field is used for CRC checksum generation.

33.2.2 CRC Polynomial register (CRC_GPOLY)

This register contains the value of the polynomial for the CRC calculation. The HIGH field contains the upper 16 bits of the CRC polynomial, which are used only in 32-bit CRC mode. Writes to the HIGH field are ignored in 16-bit CRC mode. The LOW field contains the lower 16 bits of the CRC polynomial, which are used in both 16- and 32-bit CRC modes.

Address: 4003_3000h base + 4h offset = 4003_3004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	HIGH																LOW															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	1	0	0	0	0	1

CRC_GPOLY field descriptions

Field	Description
31–16 HIGH	High Polynominal Half-word Writable and readable in 32-bit CRC mode (CTRL[TCRC] is 1). This field is not writable in 16-bit CRC mode (CTRL[TCRC] is 0).
15–0 LOW	Low Polynominal Half-word Writable and readable in both 32-bit and 16-bit CRC modes.

33.2.3 CRC Control register (CRC_CTRL)

This register controls the configuration and working of the CRC module. Appropriate bits must be set before starting a new CRC calculation. A new CRC calculation is initialized by asserting CTRL[WAS] and then writing the seed into the CRC data register.

Address: 4003_3000h base + 8h offset = 4003_3008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0		0		0	FXOR	WAS	TCRC	0							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

CRC_CTRL field descriptions

Field	Description
31–30 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
29–28 Reserved	Reserved This field is reserved. This read-only field is reserved and always has the value 0.
27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26 FXOR	Complement Read Of CRC Data Register Some CRC protocols require the final checksum to be XORed with 0xFFFFFFFF or 0xFFFF. Asserting this bit enables on the fly complementing of read data. 0 No XOR on reading. 1 Invert or complement the read value of the CRC Data register.
25 WAS	Write CRC Data Register As Seed When asserted, a value written to the CRC data register is considered a seed value. When deasserted, a value written to the CRC data register is taken as data for CRC computation. 0 Writes to the CRC data register are data values. 1 Writes to the CRC data register are seed values.
24 TCRC	Width of CRC protocol. 0 16-bit CRC protocol. 1 32-bit CRC protocol.
23–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

33.3 Functional description

33.3.1 CRC initialization/reinitialization

To enable the CRC calculation, the user must program CRC_CTRL[WAS], CRC_GPOLY, and CRC result inversion in the applicable registers. Asserting CRC_CTRL[WAS] enables the programming of the seed value into the CRC_DATA register.

After a completed CRC calculation, reasserting CRC_CTRL[WAS] and programming a seed, whether the value is new or a previously used seed value, reinitialize the CRC module for a new CRC computation. All other parameters must be set before programming the seed value and subsequent data values.

33.3.2 CRC calculations

In 16-bit and 32-bit CRC modes, data values can be programmed 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous. Noncontiguous bytes can lead to an incorrect CRC computation.

33.3.2.1 16-bit CRC

To compute a 16-bit CRC:

1. Clear CRC_CTRL[TCRC] to enable 16-bit CRC mode.
2. Write a 16-bit polynomial to the CRC_GPOLY[LOW] field. The CRC_GPOLY[HIGH] field is not usable in 16-bit CRC mode.
3. Set CRC_CTRL[WAS] to program the seed value.
4. Write a 16-bit seed to CRC[LU:LL]. CRC_DATA[HU:HL] are not used.
5. Clear CRC_CTRL[WAS] to start writing data values.
6. Write data values into CRC[LU:LL]. A CRC is computed on every data value write, and the intermediate CRC result is stored back into CRC[LU:LL].
7. When all values have been written, read the final CRC result from CRC[LU:LL].

33.3.2.2 32-bit CRC

To compute a 32-bit CRC:

1. Set CRC_CTRL[TCRC] to enable 32-bit CRC mode.
2. Write a 32-bit polynomial to CRC_GPOLY[HIGH:LOW].
3. Set CRC_CTRL[WAS] to program the seed value.
4. Write a 32-bit seed to CRC[LL].
5. Clear CRC_CTRL[WAS] to start writing data values.
6. Write data values into CRC[LL]. A CRC is computed on every data value write, and the intermediate CRC result is stored back into CRC[LL].
7. When all values have been written, read the final CRC result from CRC[LL]. The CRC is calculated bytewise, and two clocks are required to complete one CRC calculation.

33.3.3 CRC result complement

When CTRL[FXOR] is set, the checksum is complemented. The CRC result complement function outputs the complement of the checksum value stored in the CRC data register every time the CRC data register is read. When CTRL[FXOR] is cleared, reading the CRC data register accesses the raw checksum value.

Chapter 34
LPDDR2/DDR3 SDRAM Memory Controller (DDRMC)

34.1 Introduction

The memory controller supports high performance applications for 16-bit or 8-bit DDR2, or LPDDR SDRAM memories.

The features of this Memory Controller include:

- Supports interfacing to LPDDR2 and DDR3 memory types.
- Fully pipelined command, read and write data interfaces to the memory controller.
- Advanced bank look-ahead features for high memory throughput.
- Front-end interface to 2 standard AXI ports.
- A programmable register interface to control memory parameters and protocols including auto pre-charge.
- Full initialization of memory on memory controller reset.
- ECC functionality with single bit and double bit error reporting and automatic correction of single bit error events. 10 bit memory interface required for ECC (8 bit user data + 2 bits ECC). Programmable removal of ECC storage.
- Programmable memory datapath size of full memory data (16 bit) width or half memory data (8 bit) width.
- Clock frequencies from 100 MHz to 400 MHz supported.
- Back-end interface to a PHY.
- Integrates support for DDR pad calibration logic calibration in both software mode and hardware mode. Software calibration is only for debug.

34.2 Block diagram

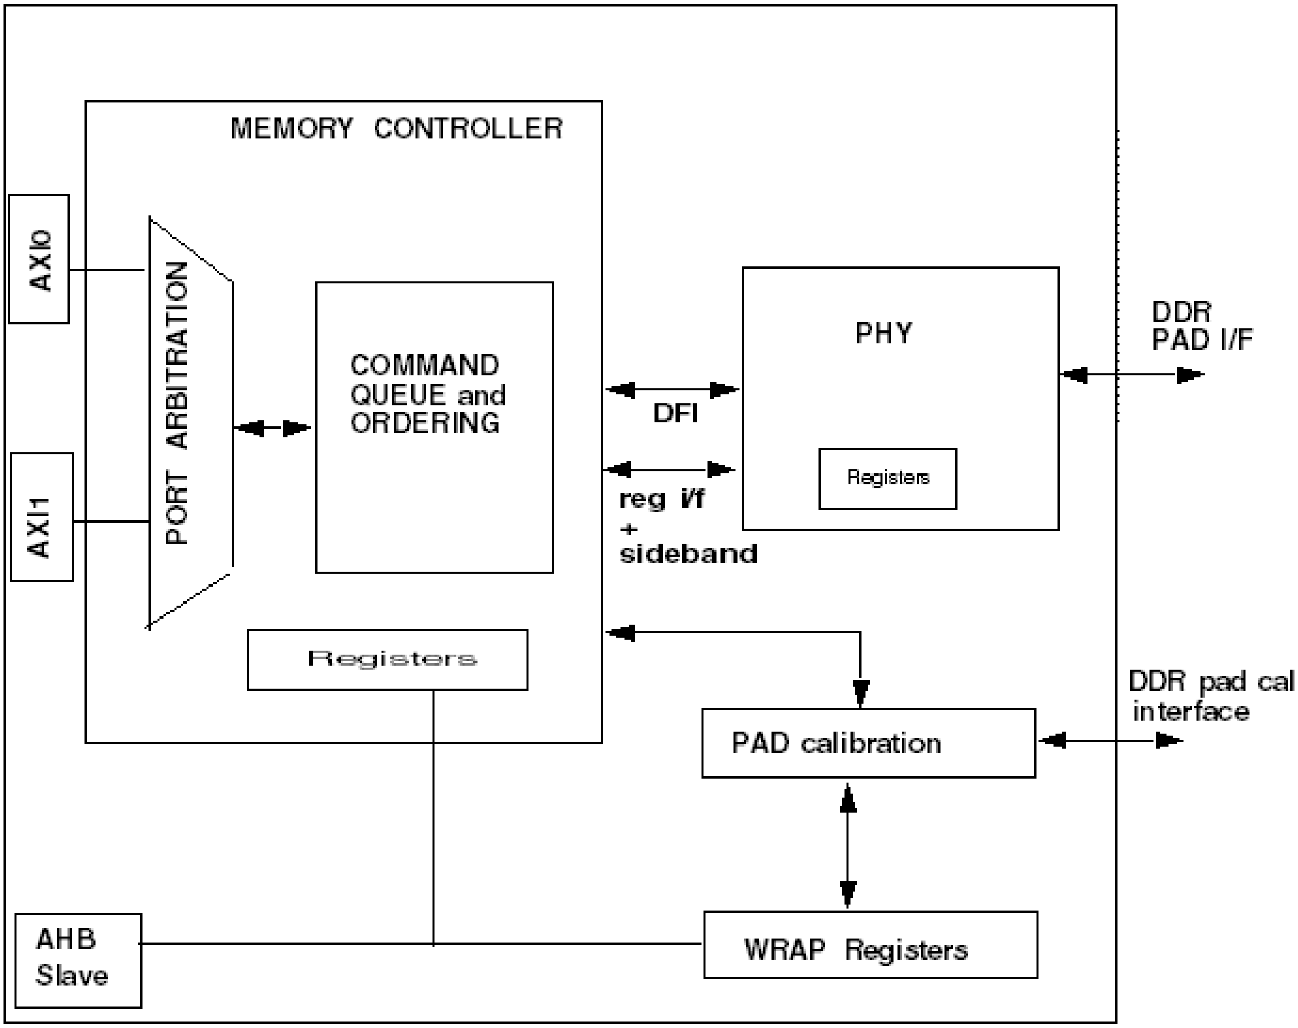

Figure 34-1. DDRMC Block Diagram

34.3 Modes of Operation

The following operating modes are available:

- LPDDR2
- DDR3

34.3.1 Low Power Modes

For details see Low Power Operation.

34.4 Signal Description

The following table lists the memory controller's external memory interface signals.

Table 34-1. Signal Properties

Name	Function	I/O	Reset
DDR_A[10:0] DDR_A[14:0]	Selects the column when DDR_CAS is asserted Selects the row when DDR_RAS is asserted.	O	0000
DDR_BA[2:0]	Selects 1 of 8 SDRAM Banks when DDR_RAS is asserted (precharge or active) or when DDR_CAS is asserted (read or write). 000 - Bank1 001 - Band2 ---------- 111 - Bank8	O	0
DDR_CAS	Column address select	O	1
DDR_CKE	Clock enable. Asserts when the clock is valid	O	0
DDR_CLK DDR_CLK	Differential clock	O	0 1
DDR_CS	Chip select	O	1
DDR_DQ[15:0]	Write or read data from the SDRAM	I/O	—
DDR_DM	Data mask: 00 No mask 01 Low byte mask enable 10 High byte mask enable 11 Low and hign byte mask enable	O	11
DDR_DQS[1:0]	Differential data strobe **Note:** Pull down is active in LPDDR2 mode only.	I/O	—
DDR_ODT	On-die-termination	O	0
DDR_RAS	Row address select	O	1
DDR_WE	Write enable	O	1
DDR_VREF	Voltage supply reference	—	—
DDR_RESET	Reset signal	O	—

34.4.1 Detailed Signal Descriptions

The following table describes the external signals in more detail with timing to DDR_CLK and how the signals interact with each other.

Table 34-2. Detailed Signal Descriptions

Signal	I/O		Description
DDR_A[15:0]	O		Provides the row address for ACTIVE commands, and the column address and AUTO PRECHARGE bit for READ/WRITE commands, to select one location out of the memory array in the respective bank. A10 is sampled during a precharge command to determine whether the PRECHARGE applies to one bank (A10 LOW) or all banks (A10 HIGH). If only one bank is to be precharged, the bank is selected by BA0, BA1 and BA2. The address outputs also provide the op-code during a MODE REGISTER SET command. BA0, BA1 and BA2 define which mode register is loaded during the MODE REGISTER SET (MRS or EMRS's)
		State Meaning	Please seeTable 34-4 for the LPDDR2 SDRAM commands.
		Timing	Assertion/Negation— Occurs synchronously with DDR_CLK
DDR_BA[2:0]	O		BA0, BA1 and BA2 define which 1 of 8 banks an ACTIVE, READ, WRITE, or PRECHARGE command is being applied to.
		Timing	Assertion/Negation— Occurs synchronously with DDR_CLK
$\overline{\text{DDR\_CAS}}$	O		Command input. Along with $\overline{\text{DDR\_CS}}$, $\overline{\text{DDR\_RAS}}$, and $\overline{\text{DDR\_WE}}$ defines the current command.
		State Meaning	Please seeTable 34-3 for the DDR3 SDRAM commands.
		Timing	Assertion/Negation— Occurs synchronously with DDR_CLK
DDR_CKE	O		CKE must be maintained high throughout READ and WRITE accesses. Input buffers, excluding DDR_CLK, $\overline{\text{DDR\_CLK}}$, and DDR_CKE, are disabled during POWER DOWN or SELF REFRESH.
		State Meaning	Asserted— Activates internal clock signals and device input buffers and output drivers. Negated—Deactivates internal clock signals and device input buffers and output drivers.
		Timing	Assertion — Asynchronous for SELF-REFRESH exit and for output disable Negation— Occurs synchronously with DDR_CLK
DDR_CLK $\overline{\text{DDR\_CLK}}$	O		DDR_CLK and $\overline{\text{DDR\_CLK}}$ are differential clock outputs. All address and control output signals are sent on the crossing of the positive edge of DDR_CLK and the negative edge of $\overline{\text{DDR\_CLK}}$. Output data is referenced to the crossing of DDR_CLK and $\overline{\text{DDR\_CLK}}$ (both directions of crossing).
		Timing	Command signals are synchronously with the rising edge of this clock. The data signals can change on both the rising and falling edge of the clock.
$\overline{\text{DDR\_CS}}$	O		$\overline{\text{DDR\_CS}}$ provides for external chip selection on systems with multiple chips. $\overline{\text{DDR\_CS}}$ is considered part of the command code.
		State Meaning	Asserted— Commands for the selected chip will occur Negated—All commands are masked.
		Timing	Assertion/Negation— Occurs synchronously with DDR_CLK
DDR_D[15:0]	I/O		Data bus
		Timing	Assertion/Negation— Occurs on both crossing of DDR_CLK and $\overline{\text{DDR\_CLK}}$ on write command. Synchronous with DDR_DQS input on read command.

Table continues on the next page...

Table 34-2. Detailed Signal Descriptions (continued)

Signal	I/O	Description	
DDR_DM[1:0]	O	Output mask signal for write data. During Reads, DDR_DM may be driven high, low, or floating.	
		State Meaning	Asserted— Data is written to SDRAM Negation— Data is masked
		Timing	Assertion/Negation— Occurs on both crossing of DDR_CLK and DDR_CLK.
DDR_DQS[1:0]	I/O	Edge-aligned with read data, centered in write data. Used to capture data.	
		State Meaning	Asserted— Similar to a clock signal, the edges are more important than being asserted or negated.
		Timing	Assertion/Negation—Occurs on both crossing of DDR_CLK and DDR_CLK on write command. Asynchronous with DDR_CLK and DDR_CLK on read command.
DDR_ODT	O	DDR_ODT enables termination resistance internal to the DDR2 SDRAM.	
		State Meaning	Asserted— Enable termination resistance Negation— Disable termination resistance Please see Table 34-3 for DDR3 SDRAM commands.
		Timing	Assertion/Negation— Occurs synchronously with DDR_CLK
DDR_RAS	O	Command input. Along with DDR_CS, DDR_CAS, and DDR_WE defines the current command.	
		State Meaning	Please see Table 34-3 for DDR3 SDRAM commands.
		Timing	Assertion/Negation— Occurs synchronously with DDR_CLK.
DDR_WE	O	Command input. Along with DDR_CS, DDR_CAS, and DDR_RAS defines the current command.	
		State Meaning	Please see Table 34-3 for DDR3 SDRAM commands.
		Timing	Assertion/Negation— Occurs synchronously with DDR_CLK. Refer device datasheet for the PU/PD details.
DDR_VREF	—	SDRAM reference voltage. Reference voltage for differential I/O pad cells should be half the voltage of the memory used in the system. For example, 1.5 V DDR3 results in an DDR_VREF of 0.75 V and 1.2 V LPDDR2 results in an DDR_VREF of 0.6 V. See the device's datasheet for the voltages and tolerances for the various memory modes.	
DDR_RESET	O	DDR3 memory reset signal.	
		State Meaning	Assertion: Memory is in Reset Negation: Memory is in normal operating mode
		Timing	ASSERTS asynchronously and de-assertion is synchronour to DDR_CLK per JEDEC timings

Note

1. CKE is HIGH for all commands shown except SELF REFRESH.
2. BA0--BA1 select either the Base or the Extended Mode Register (BA0 = 0, BA1 = 0 selects Mode Register; BA0 = 1, BA1 = 0 selects Extended Mode Register; other combinations of BA0--BA1 are reserved; A0--A13 provide the op--code to be written to the selected Mode Register.
3. BA0--BA1 provide bank address and A0--A13 provide row address.
4. BA0--BA1 provide bank address; A0--Ai provide column address; A10 HIGH enables the auto precharge feature (non-persistent), A10 LOW disables the auto precharge feature.
5. A10 LOW: BA0--BA1 determine which bank is precharged. A10 HIGH: all banks are precharged and BA0--BA1 are "Don't Care."
6. This command is AUTO REFRESH if CKE is HIGH; SELF REFRESH if CKE is LOW.

7. Internal refresh counter controls row addressing; all inputs and I/Os are "Don't Care" except for CKE.
8. Applies only to read bursts with autoprecharge disabled; this command is undefined (and should not be used) for read bursts with autoprecharge enabled, and for write bursts.
9. DESELECT and NOP are functionally interchangeable.
10. Used to mask write data, provided coincident with the corresponding data.
11. Operation or timing that is not specified is illegal and after such an event, in order to guarantee proper operation, the DRAM must be powered down and then restarted through the specified initialization sequence before normal operation can continue.
12. VREF must be maintained during Self Refresh operation.

Exit PD, SREF, DPD	L	H	H	X										
				X										

Note

1. All LPDDR2 commands are defined by states of CS_n, CA0, CA1, CA2, CA3, and CKE at the rising edge of the clock. CA refers to command/address slice.
2. For LPDDR2 SDRAM, Bank addresses BA0, BA1, BA2 (BA) determine which bank is to be operated upon.

3. AP is significant only to SDRAM.
4. AP "high" during a READ or WRITE command indicates that an auto-precharge will occur to the bank associated with the READ or WRITE command.
5. "X" means "H or L (but a defined logic level)"
6. Self refresh exit and Deep Power Down exit are asynchronous.
7. VREF must be between 0 and VDDQ during Self Refresh and Deep Power Down operation.
8. CAxr refers to command/address bit "x" on the rising edge of clock.
9. CAxf refers to command/address bit "x" on the falling edge of clock.
10. CS_n and CKE are sampled at the rising edge of clock.
11. Per Bank Refresh is only allowed in devices with 8 banks.
12. The least-significant column address C0 is not transmitted on the CA bus, and is implied to be zero.

34.5 Memory map and register description

NOTE

Register read or write for any register in the DDR controller requires the DDRMC clock to be configured from CCM_CCSR [DDRC_CLK_SEL] in addition to enabling the clock from the clock gating register: CCM_CCGR6[CG110].

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_CR00 field descriptions

Field	Description
31–16 VERSION	Holds the controller version number.
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–8 DRAM_CLASS	Defines the mode of operation of the controller. Only the following settings are applicable. All other settings are reserved. 0101 LPDDR2 (supports burst lengths of 4 or 8) 0110 DDR3 (supports burst length of 8 only)
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 START	Initiate command processing in the controller. Set to 1 to initiate.

34.5.2 Control Register 1 (DDRMC_CR01)

Address: 400A_E000h base + 4h offset = 400A_E004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															MAX_CS_REG
W

W																
Reset	0	0	0	0	1	1	0	1	0	0	0	1	0	0	0	0

DDRMC_CR01 field descriptions

Field	Description
31–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 MAX_CS_REG	Displays the maximum number of chip selects configured for this memory controller
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DDRMC_CR01 field descriptions (continued)

Field	Description
11–8 MAX_COL_REG	Defines the maximum width of column address in the DRAM memories. This value can be used to set the col_diff parameter. This parameter is read-only. col_diff = max_col_reg -(number of column bits in memory)
7–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–0 MAX_ROW_REG	Defines the maximum width of the memory address bus for the memory controller. **NOTE:** For LPDDR2 memory systems (dram_class = 'b0101), the parameter row_diff holds the difference between the maximum number of row pins configured and the actual number of row pins being. This value can be used to set the row_diff parameter. row_diff = max_row_reg - (number of row bits in memory).

34.5.3 Control Register 2 (DDRMC_CR02)

Address: 400A_E000h base + 8h offset = 400A_E008h

Bit	31–24	23–0
R	0	TINIT
W

DDRMC_CR10 field descriptions

Field	Description
31–0 TRST_PWRON	Defines the number of memory clocks that memory will be held in reset during the power-on initialization sequence. This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = ’b0110)

34.5.12 Control Register 11 (DDRMC_CR11)

Address: 400A_E000h base + 2Ch offset = 400A_E02Ch

Bit	31–0
R/W	CKE_INACTIVE
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

DDRMC_CR11 field descriptions

Field	Description
31–0 CKE_INACTIVE	Defines the number of memory clocks after reset before the CKE signal will be active. This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class =b0110) **NOTE:** For the high-speed controller architecture, the observed minimum values may be one controller clock greater than the programmed value due to the nature of the half rate clocking

34.5.13 Control Register 12 (DDRMC_CR12)

Address: 400A_E000h base + 30h offset = 400A_E030h

Bit	31–16	15–13	12–8	7–6	5–0
R	0	0	WRLAT	0	CASLAT_LIN
W					
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0 0	0 0 0 0 0	0 0	0 0 0 0 0 0

DDRMC_CR12 field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 WRLAT	Defines the write latency from when the write command is issued to the time the write data is presented to the DRAM memories, in controller clocks.
7–6 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
5–0 CASLAT_LIN	Sets latency from read command send to data receive from/to controller. Bit (0) is half-cycle increment and the upper bits define memory CAS latency for the controller.

34.5.14 Control Register 13 (DDRMC_CR13)

Address: 400A_E000h base + 34h offset = 400A_E034h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R/W	TRC								TRRD							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0			TCCD					0					TBST_INT_INTERVAL		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_CR13 field descriptions

Field	Description
31–24 TRC	Defines the DRAM period between active commands for the same bank, in memory clocks.
23–16 TRRD	Defines the DRAM activate to activate delay to different bank groups, in memory clocks.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 TCCD	Defines the minimum delay between CAS commands, in memory clocks. This value is loaded into a counter when a memory burst is issued and a new command may be issued when the counter reaches 0. **NOTE:** Since the counter is initially loaded with the value “tccd-1”, if this parameter is cleared to ’b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to ’b1 as a minimum.
7–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–0 TBST_INT_ INTERVAL	DRAM burst interrupt interval value in cycles.

34.5.15 Control Register 14 (DDRMC_CR14)

Address: 400A_E000h base + 38h offset = 400A_E038h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0		TFAW						0			TRP					0				TWTR				TRAS_MIN							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_CR14 field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DDRMC_CR14 field descriptions (continued)

Field	Description
29–24 TFAW	Defines the DRAM tFAW term, in memory clocks
23–21 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
20–16 TRP	Defines the DRAM pre-charge / preactivate command time, in memory clocks.If the memory specification defines both a single-bank and an all-banks pre-charge value, this parameter should be programmed to the single-bank value and the trp_ab parameter should be programmed to the all-banks value.
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–8 TWTR	Sets the number of memory clocks needed to switch from a write to a read operation.
7–0 TRAS_MIN	Defines the DRAM minimum row activate time, in memory clocks

34.5.16 Control Register 15 (DDRMC_CR15)

Address: 400A_E000h base + 3Ch offset = 400A_E03Ch

Bit	31–16	15–0
R	0	0
W		
Reset	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

DDRMC_CR15 field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

34.5.17 Control Register 16 (DDRMC_CR16)

Address: 400A_E000h base + 40h offset = 400A_E040h

Bit	31–29	28–24	23–20	19–16	15–0
R	0	TMRD	0	TRTP	0
W					
Reset	0 0 0	0 0 0 0 0	0 0 0 0	0 0 0 0	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

DDRMC_CR16 field descriptions

Field	Description
31–29 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
28–24 TMRD	Defines the minimum number of memory clocks required between two mode register write commands. This is the time required to complete the write operation to the mode register. There are two parameters that control the timing after a mode register write: tmod and tmrd. This parameter (tmrd) is typically the shorter of the two timing delays. The MC will wait this delay after a mode register command before sending the next mode register command. The MC does not need to wait for the longer tmod timer to expire since termination is not used for mode register commands. **NOTE:** For LPDDR2 memory systems (dram_class = 'b0101), this parameter should be programmed to the tMRW value from the memory specification
23–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–16 TRTP	The meaning of this parameter depends on the memory system being used: • For LPDDR2 memories: Program to the tRTP (read to pre-charge time) value from the memory specification. • For DDR3 memories: Program to the tRTP (read to pre-charge time) value from the memory specification
15–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

34.5.18 Control Register 17 (DDRMC_CR17)

Address: 400A_E000h base + 44h offset = 400A_E044h

<table>
<tr><td>Bit</td><td>31</td><td>30</td><td>29</td><td>28</td><td>27</td><td>26</td><td>25</td><td>24</td><td>23</td><td>22</td><td>21</td><td>20</td><td>19</td><td>18</td><td>17</td><td>16</td><td>15</td><td>14</td><td>13</td><td>12</td><td>11</td><td>10</td><td>9</td><td>8</td><td>7</td><td>6</td><td>5</td><td>4</td><td>3</td><td>2</td><td>1</td><td>0</td></tr>

</table>

DDRMC_CR17 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24–8 TRAS_MAX	Defines the DRAM maximum row active time, in memory clocks.The user should set this value to the timing parameter in the memory specification. In practical use, the Memory Controller will use the value in this parameter with adjustments made for write recovery time, memory burst length and any internal delays if required
7–0 TMOD	Defines the number of memory clocks of delay after a mode register write to any non-mode register write command. For write leveling, this is defined as the number of memory clocks of wait time after a MRS command to the ODT enable. There are two parameters that control the timing after a mode register write: tmod and tmrd. This parameter (tmod) is typically the longer timing delay (defined by the memory specification) and controls the spacing of a mode register command to any other memory command. The MC will wait this delay after a mode register command before sending any other command to memory since the controller has no way of knowing whether or not termination (ODT) will be used. **NOTE:** There are two parameters that control the timing after a mode register write: tmod and tmrd. This parameter (tmod) is typically the longer timing delay (defined by the memory specification) and controls the spacing of a mode register command to any other memory command. The MC will wait this delay after a mode register command before sending any other command to memory since the controller has no way of knowing whether or not termination (ODT) will be used.

34.5.19 Control Register 18 (DDRMC_CR18)

Address: 400A_E000h base + 48h offset = 400A_E048h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DDRMC_CR18 field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–8 TCKESR	Defines the minimum number of cycles that CKE must be held low during selfrefresh, in memory clocks. If the memory specification does not define a tCKESR, then the tckesr parameter should be programmed to the tCKE value from the memory specification
7–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–0 TCKE	Defines the minimum CKE pulse width, in memory clocks

34.5.20 Control Register 19 (DDRMC_CR19)

Address: 400A_E000h base + 4Ch offset = 400A_E04Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DDRMC_CR20 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 AP	Enables auto pre-charge mode for DRAM memories **NOTE:** This parameter may not be modified after the start parameter has been asserted.When using auto-precharge per command,this parameter must be cleared to ’b0. 0 Disable auto pre-charge mode. Memory banks will stay open until another request requires this bank, the maximum open memory clocks has elapsed,or a refresh command closes all the blanks. 1 Enable auto pre-charge mode. All read and write transactions must be terminated by an auto pre-charge command. If a transaction consists of multiple read or write bursts, only the last command is issued with an auto pre-charge.
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 WRITEINTERP	Defines whether the memory controller can interrupt a write burst with a read command. Some memories do not allow this functionality. • For LPDDR2 memories: This parameter must be cleared to ’b0. • For DDR3 memories: This parameter must be cleared to ’b0. For all memory types: 0 The memory does not support read commands interrupting write commands. 1 The memory does support read commands interrupting write commands
15–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

34.5.22 Control Register 21 (DDRMC_CR21)

Address: 400A_E000h base + 54h offset = 400A_E054h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0							TRAS_ LOCKOUT	0							CCMAP
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_CR21 field descriptions

Field	Description
31–24 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
23–16 TRCD_INT	Defines the DRAM RAS to CAS delay, in memory clocks.
15–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 TRAS_ LOCKOUT	Defines the tRAS lockout setting for the DRAM memory, in memory clocks. tRAS lockout allows the memory controller to execute auto pre-charge commands before the tras_min_X parameter has expired. Note: This parameter may only be applicable to DDR1 memory systems (dram_class = 0000). 0 tRAS lockout not supported by memory. 1 tRAS lockout supported by memory.
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 CCMAP	Enables concurrent auto pre-charge. Some DRAM memories do not allow one bank to be auto pre-charged while another bank is reading or writing. The JEDEC standard allows concurrent auto precharge. The user should set this parameter if the DRAM memory supports this feature. Note: This parameter can only be set if the memory supports concurrent AP for all transactions. Some memories only support concurrent AP for writes. In this case, these memories require that reads to the same CS cannot be issued before the tWR delay has expired. If the memories being used do not support CCMAP for all transactions, CCMAP must be cleared to 0, disabling CCMAP for all transfers. 0 Disable concurrent auto precharge. 1 Enable concurrent auto precharge.

34.5.23 Control Register 22 (DDRMC_CR22)

Address: 400A_E000h base + 58h offset = 400A_E058h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DDRMC_CR22 field descriptions

Field	Description
31–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–16 TDAL	Defines the auto pre-charge write recovery when auto pre-charge is enabled, in memory clocks. This is defined internally as tRP (pre-charge time) + auto pre-charge write recovery time.
15–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

34.5.24 Control register 23 (DDRMC_CR23)

Address: 400A_E000h base + 5Ch offset = 400A_E05Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0					BSTLEN			0				TMRR				TDLL															
W																																
Reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_CR23 field descriptions

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–24 BSTLEN	Defines the memory burst length encoding that will be programmed into the DRAM memories at initialization. The mode is programmed in the dram_class parameter. The reset value of this bit can change after reset based on internal logic. All settings except 010 and 011 are reserved. Note: For this memory controller, the user is advised to run in 8 word mode for best performance. Note: This parameter will be cleared to 0x0 on reset, but will change to the default value on the first controller clock edge after reset. Note: The reset value of this bit can change after reset based on internal logic. 010 4 memory words. Applicable for these memory systems: LPDDR2 (dram_class = 0101). 011 8 memory words. Applicable for these memory systems: LPDDR2 (dram_class = 0101) DDR3 (dram_class = 0110)
23–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–16 TMRR	Defines the DRAM tMRR term, in memory clocks. This parameter is only applicable when the MC is programmed for the following memory systems: LPDDR2 (dram_class = 0101)

Table continues on the next page...

DDRMC_CR23 field descriptions (continued)

Field	Description
15–0 TDLL	Defines the DRAM DLL lock delay, in memory clocks. This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 0110). Note: For DDR3 memory systems (dram_class = 0110), this parameter is only applicable during a frequency scaling procedure where is it defined as 512 clocks.

34.5.25 Control Register 24 (DDRMC_CR24)

Address: 400A_E000h base + 60h offset = 400A_E060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0											TRP_AB				
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_CR24 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 ADD_MIR	Indicates which chip selects support address mirroring. This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = ’b0110) 0 Standard pinout (for each chip select). 1 Mirrored wiring (for each chip select).
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 DIMM_EN	Enables registered DIMM operations to control the address and command pipeline of the controller. **NOTE:** For this controller, when the MC is programmed for DDR3 memory systems (dram_class = 0110), enabling this bit is not sufficient for registered DIMM support. 0 Normal operation 1 Enable registered DIMM operation
15–5 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
4–0 TRP_AB	Defines the DRAM TRP time for all banks, in memory clocks. The memory specification defines both a single-bank and an all-banks pre-charge value, this parameter should be programmed to the all-banks value and the trp parameter should be programmed to the single-bank value. If the memory specification

Table continues on the next page...

DDRMC_CR24 field descriptions (continued)

Field	Description
	does NOT specify an all-banks pre-charge value, both parameters should be programmed to the same value.

34.5.26 Control Register 25 (DDRMC_CR25)

Address: 400A_E000h base + 64h offset = 400A_E064h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																AREF
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_CR25 field descriptions

Field	Description
31–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 TREF_EN	Issue auto-refresh commands to the DRAMs at the interval defined in the TREF parameter. Set to 1 to Enables refresh commands. If command refresh mode is configured,then refresh commands will be automatically issued based on the tref parameter value and any refresh commands sent through the command interface or the register interface. Refreshes will still occur even if the DRAM memories have been placed in power-down state. Note: Even with this parameter cleared to 0, some refresh commands may still be issued to memory. This only controls the automatic refreshes issued every tref memory clocksenable.

Table continues on the next page...

DDRMC_CR25 field descriptions (continued)

Field	Description
	0 Disable refresh commands. 1 Enable refresh commands.
15–9 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
8 AUTO_RFM	Sets the mode for when the automatic refresh will occur. If the auto_refmode parameter is set and a refresh is required to memory, the memory controller will delay this refresh until the end of the current transaction (if the transaction is fully contained inside a single page), or until the current transaction hits the end of the current page. 0 Issue refresh on the next memory burst boundary, even if the current command is not complete. 1 Issue refresh on the next command boundary.
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 AREF	Initiates an automatic refresh to the DRAM memories based on the setting of the auto_refmode parameter. If there are any open banks when this parameter is set, the Memory Controller will automatically close these banks before issuing the auto-refresh command. This parameter is write-only and will always read back as 0x0. 0 No action. 1 Issue refresh to the DRAM memories.

34.5.27 Control Register 26 (DDRMC_CR26)

Address: 400A_E000h base + 68h offset = 400A_E068h

Bit	31–16	15–10	9–0

DDRMC_CR28 field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–0 TREF_INT	Sets the time delay, in memory clocks, between when refresh commands are issued to different chip selects. If tref_int is cleared to 000, then the refresh per chip select logic will be disabled and all chip selects will be refreshed simultaneously. The tref_int parameter value must be less than the trfc parameter value.

34.5.30 Control Register 29 (DDRMC_CR29)

Address: 400A_E000h base + 74h offset = 400A_E074h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DDRMC_CR29 field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–0 TPDEX	Defines the DRAM power-down exit command period, in memory clocks. For LPDDR2 memories: Program to the tXP value from the memory specification. For DDR3 memories: There are two parameters to specify power-down exit time, tpdex and txpdll. This parameter should be programmed to the tXP value from the memory specification. The memory controller will use this value for power-down exit time when the parameter mr0_data_X [12] bit (Dll Control for PreCharge) is set to 1 (fast exit).

34.5.31 Control Register 30 (DDRMC_CR30)

Address: 400A_E000h base + 78h offset = 400A_E078h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0																TXPDLL															
W

DDRMC_CR30 field descriptions

Field	Description
31–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–0 TXPDLL	Defines the DRAM power-down exit command period, in memory clocks. There are two parameters to specify power-down exit time, tpdex and txpdll. This parameter should be programmed to the tXPDLL value from the memory specification. The memory controller will use this value for powerdown exit time when the parameter mr0_data_X [12] bit (Dll Control for PreCharge) is cleared to 0 (slow exit). This parameter is only applicable when the MC is programmed for the following memory systems: DDR3 (dram_class = 0110)

34.5.32 Control Register 31 (DDRMC_CR31)

Address: 400A_E000h base + 7Ch offset = 400A_E07Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TXSNR																TXSR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_CR31 field descriptions

Field	Description
31–16 TXSNR	Defines the DRAM time from a selfrefresh exit to a command that does not require the memory DLL to be locked, in memory clocks. Note: For DDR3 memory systems (dram_class = 0110), this parameter should be programmed to the tXS value from the memory specification. And since the DDR3 JEDEC specification defines tXPR = max (tXS, 5*tCK), this parameter can also be used to account for the memory timing value tXPR. The user must set the txsnr parameter to at least 0x5 for this relationship.

Table continues on the next page...

DDRMC_CR31 field descriptions (continued)

Field	Description
15–0 TXSR	Defines the DRAM time from a selfrefresh exit to an active command that requires the memory DLL to be locked, in memory clocks. The meaning of this parameter depends on the memory system being used: • For LPDDR2 memories: Set this parameter and the txsnr parameter to the same value. • For DDR3 memories: Set this parameter to the difference between the tXSDLL and tRCD values in the memory specification.

34.5.33 Control Register 32 (DDRMC_CR32)

Address: 400A_E000h base + 80h offset = 400A_E080h

DDRMC_CR33 field descriptions

Field	Description
31–27 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
26–24 CKE_DELAY	Additional cycles to delay CKE for status reporting.
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
16 EN_QK_SREF	When this bit is set to 1, the memory initialization sequence may be interrupted and the memory may enter self-refresh mode. This is used to place the memories into self-refresh mode when a power loss is detected during the initialization process. Setting this parameter does not initiate a self-refresh entry during initialization. However, if a self-refresh entry is requested during initialization, it will only occur if this parameter is also set to 1. 0 Continue memory initialization. 1 Interrupt memory initialization and enter self-refresh mode.
15–9 Reserved	This field is reserved.
8 SREF_EX_ NOREF	When a self-refresh exit command is executed, an automatic refresh is requested. By setting this bit, the automatic refresh request is inhibited. 0 Allow automatic refresh. 1 Inhibit automatic refresh.
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 PWUP_SREF_ EX	Allows the controller to exit low power by executing a self-refresh exit instead of the full memory initialization. This parameter provides a means to skip full initialization when the DRAM memories are in a known self-refresh state. 0 Disable. 1 Enable. If this option is being used.

34.5.35 Control Register 34 (DDRMC_CR34)

Address: 400A_E000h base + 88h offset = 400A_E088h

DDRMC_CR35 field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

27–24
LP_ARBST
	Low power arbiter state status register, which defines which interface has control of the LPC module. This parameter is readonly.
	• Bit [3] - Software lock indicator
	  • 0 - No lock is in place
	  • 1 - The software programmable interface has locked the arbiter. Only a low power command issued through the register interface without the lock bit set, or a high-priority command on the external pin interface can clear this lock.

23–22 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
21–16 LP_ST	Note: If an active power-down was requested, the memory will enter either active or pre-charge power-down depending on the state of the rows. If there are no active rows, pre-charge power-down will be entered. Even if pre-charge powerdown is used, this parameter will reflect the requested active power-down state. Low power state status register. This value is also reflected in the output signal lp_ext_state

Table continues on the next page...

100010 = Active Power-Down with Memory Clock Gating, with lock
100011 = Pre-Charge Power-Down, with lock
100100 = Pre-Charge Power-Down with Memory Clock Gating, with lock
100101 = Self-Refresh, with lock
100110 = Self-Refresh with Memory Clock Gating, with lock
100111 = Self-Refresh with Memory and Controller Clock Gating, with lock
All other settings are Reserved</td></tr>
<tr><td>15–8
LP_CMD</td><td>Defines the low power command requested through the software programmable interface. When this command is completed, the low power command complete interrupt (bit 10) in the INT_STAT parameter will be set to 1. Re-programming attempts to this parameter until the interrupt is set will be ignored. This parameter is write-only and will always read back as 0x0. The bits are defined as follows:
Bit [7] = Lock.
0 = No action
1 = Lock command
Bit [6] = Controller clock gating.
0 = No action
1 = Gate the controller clock
Bit [5] = Memory clock gating.
0 = No action
1 = Gate the memory clock
Bits [4:2] = Low power state.
000 = Active power-down
001 = Pre-charge power-down
010 = Self-refresh
All other settings are Reserved
Bit [1] = Entry command.
0 = No action
1 = Enter the specified state
Bit [0] = Exit command.
0 = No action
1 = Exit the specified state</td></tr>
</table>

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_CR36 field descriptions

Field	Description
31–18 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
17–16 LP_AMEMEN	Enables memory clock gating when entering each of the low power modes automatically. A low power mode is only entered automatically if the associated bit in the lpauto parameter is also set to 1 when the idle timer expires. Note: This parameter does not apply to the ?Self-Refresh with Memory and Controller Clock Gating,? low power mode. If this timer expires and lpauto [2] is set to 1, the memory clock will always be gated. • Bit [1] = Self-Refresh • Bit [0] = Power-Down Note: The MC will issue entry into active power-down or pre-charge powerdown depending on the state of the rows at the time the command is required. This differentiation is only applicable when the MC is programmed for the following memory systems: LPDDR2 (dram_class = ’b0101). 0 (For all bits) Disable memory clock gating when automatically entering into this low power state. 1 (For all bits) Enable memory clock gating when automatically entering into this low power state.
15–11 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
10–8 LP_AEXEN	Enables automatic exit from each of the low power states when the associated idle timer expires. The low power state will be exited automatically when a read or write command enters the command queue in the memory controller core. Note: Automatic exit will occur regardless of the interface that initiated the low power state entry (external pin interface, software programmable interface or automatic interface). Note: Automatic exit will not interrupt a command sequence such as frequency scaling or ZQ calibration, or a shutdown. • Bit [2] = Self-Refresh with Memory and Controller Clock Gating

Table continues on the next page...

DDRMC_CR36 field descriptions (continued)

Field	Description
	• Bit [1] = Self-Refresh • Bit [0] = Power-Down Note: Note: For power-down, enabling the bit will cause exit from either the active power-down or pre-charge power-down modes. This differentiation is only applicable when the MC is programmed for the following memory systems:LPDDR2 (dram_class = 0101). 0 (For all bits) Disable automatic exit from this low power state. 1 (For all bits) Enable automatic exit from this low power state. The state will be exited automatically when a read or write command enters the memory controller core command queue.
7–3 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
2–0 LPAUTO	Enables automatic entry into each of the low power states when the associated idle timer expires.For power-down or self-refresh modes, the memory clock will also be gated when the timer expires if the associated bit in the lp_amemen parameter is set to 1. For “Self-Refresh with Memory and Controller Clock Gating,” memory clock gating will always be included. • Bit [2] = Self-Refresh with Memory and Controller Clock Gating • Bit [1] = Self-Refresh • Bit [0] = Power-Down Note: For power-down, the MC will issue entry into active power-down or pre-charge power-down depending on the state of the rows at the time the command is required. This differentiation is only applicable when the MC is programmed for the following memory systems:LPDDR2 (dram_class = 0101). 0 (For all bits) Disable automatic entry into this low power state. 1 (For all bits) Enable automatic entry into this low power state. The state will be entered automatically when the proper counters expire.

34.5.38 Control Register 37 (DDRMC_CR37)

Address: 400A_E000h base + 94h offset = 400A_E094h

Bit	31–24	23–16	15–12	11–0

DDRMC_CR37 field descriptions

Field	Description
31–24 LP_A_SR_MC_IDL	“Self-Refresh with Memory and Controller Clock Gating” auto entry refresh cycles. This parameter defines the number of refresh cycles that can elapse before the memory controller will automatically issue an entry into the “Self-Refresh with Memory and Controller Clock Gating” low power state. Clearing this parameter to 0x0 disables automatic entry, even if the associated bit in the lpauto parameter is set to 1.
23–16 LP_A_SR_IDL	“Self-Refresh” or “Self-Refresh with Memory Clock Gating” auto entry refresh cycles. This parameter defines the number of refresh cycles that can elapse before the memory controller will automatically issue an entry into the “Self-Refresh” or “Self-Refresh with Memory Clock Gating” low power state. Clearing this parameter to 0x0 disables automatic entry, even if the associated bit in the lp_auto_entry_en parameter is set to 1.

Table continues on the next page...

DDRMC_CR37 field descriptions (continued)

Field	Description
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–0 LP_A_PD_IDL	Defines the power-down mode auto entry controller clocks. This parameter relates to all of the following states: • “Active Power-Down” • “Active Power-Down with Memory Clock Gating” • “Pre-Charge Power-Down” • “Pre-Charge Power-Down with Memory Clock Gating” The MC will issue an active power-down unless all of the pages are closed. In that case, the MC will issue a pre-charge power-down. This parameter defines the number of idle controller clocks that can elapse before the memory controller will automatically issue an entry into the approprte powerdown low power state. This value will be loaded into the associated counter when a command enters the command queue. Clearing this parameter to 0x0 disables automatic entry, even if the associated bit in the lp_auto_entry_en parameter is set to 1.

34.5.39 Control Register 38 (DDRMC_CR38)

Field	Description
31–1 Reserved	This read-only field is reserved and always has the value 0.
0 PHY_INI_STRT_ INI_DIS	Disables the assertion of the MC frequency change request during DFI initialization. The value of this parameter does not affect the assertion of the frequency change request signal during the frequency scaling operation. The frequency change request signal is optional and only used by MCs that support the frequency change protocol. 0 Allow the frequency change request signal to assert. 1 Disable the frequency change request signal assertion.

DDRMC_CR45 field descriptions

Field	Description
31–26 Reserved	This read-only field is reserved and always has the value 0.
25–0 WRMD	Issues mode register write(s) to the specified mode register(s) and memories. When the write has been completed, the mode register write complete interrupt (bit 21) will be set to 1 in the int_stat parameter. Any errors will be reported in the MRW_STAT bits. This parameter will be reset to 0x0 on the controller clock after it is changed and can not be reprogrammed until the interrupt occurs. **NOTE:** Software internal logic can also update this bit.

34.5.47 Control Register 46 (DDRMC_CR46)

Address: 400A_E000h base + B8h offset = 400A_E0B8h

Bit	31–25	24–8	7–0
R	0	RMD	MRW_STAT
W			
Reset	0 0 0 0 0 0 0	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0 0 0 0 0

DDRMC_CR46 field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value 0.
24–8 RMD	Holds the memory mode register 2 data written during memory initialization, during a frequency scaling procedure, or when the WRMD parameter bit [25] is asserted with bit [16] or bit [17] set to 1. The meaning of this parameter depends on the memory system being used: • For LPDDR2 memories: (MR2) • For DDR3 memories: (MR2) **NOTE:** Software internal logic can also update this bit.
7–0 MRW_STAT	Provides status of the write mode register request issued through the assertion of WRMD(write_modereg) bit . This parameter is read only and is valid when the mode register write complete interrupt (bit 21) is set to 1 in the int_stat parameter. • Bits [7:3] = Reserved • Bit [2] = Reserved

Table continues on the next page...

DDRMC_CR46 field descriptions (continued)

Field	Description
	• Bit [1] = A mode register write was requested for the PASR mode registers (MR16, MR17) when the memory controller is not programmed for LPDDR2 memory systems (dram_class is not programmed to 0101). • Bit [0] = WRMD(write_modereg) programming error. This bit will be set if no mode register write type is specified (WRMD bits [23:16]) but the mode register write was triggered (WRMD bit [25] = 1).

34.5.48 Control Register 47 (DDRMC_CR47)

Address: 400A_E000h base + BCh offset = 400A_E0BCh

DDRMC_CR47 field descriptions

Field	Description
31–24 REF_AU_ TMPCHK	Sets the maximum number of refresh commands between automatic mode register reads of MR4. Setting this parameter to 0x0 will disable automatic polling of the MR4. On each expiration of this counter, the MR4 for the next chip select in order will be read and stored into the relevant bits of the auto_tempchk_val parameter. This parameter is only applicable when the MC is programmed for the following memory systems: LPDDR2 (dram_class = 0101)
23–20 Reserved	This read-only field is reserved and always has the value 0.
19–16 AU_TMPCHK_ VAL	Holds the data read from MR4 (bits OP7, OP2, OP1 and OP0) for all chip selects. This information is gathered from the LPDDR2 memories automatically through MRR commands. The frequency of updates to this parameter is defined in the refresh_per_auto_tempchk parameter. This parameter is read-only. • Bits [3:0] = MR4 data for CS 0. This parameter is only applicable when the MC is programmed for the following memory systems: • LPDDR2 (dram_class = 0101)
15–0 PERI_MRR_DA	Data and chip returned from the mode register read issued as a result of setting the bit RMD [16] to 1. The contents of this parameter are only valid when the peripheral mode register read complete interrupt (bit 18) in the int_stat parameter is set to 1. This parameter is read-only. • Bits [15:8] = MRR chip information • Bits [7:0] = Mode register data This parameter is only applicable when the MC is programmed for the following memory systems: LPDDR2 (dram_class = 0101)

34.5.49 Control Register 48 (DDRMC_CR48)

DDRMC_CR51 field descriptions

Field	Description
31–16 MR3_DA0	Holds the memory mode register 3 data for chip select 0 written during memory initialization or when the WRMD parameter bit [25] is asserted with bit [16] or bit [17] set to 1. The meaning of this parameter depends on the memory system being used: • For LPDDR2 memories: (MR3) • For DDR3 memories: (MR3) **NOTE:** Note: When programmed for DDR3 memory systems (dram_class = 0110), bit [2] of MR3 cannot be programmed through this parameter. This bit is controlled by the read leveling state machine.
15–0 MR_SINDA0	Holds the data to be programmed into a single memory mode register for chip select 0. This parameter is used when the WRMD parameter bit [25] is asserted with bit [23] is set to 1. The WRMD parameter will specify which mode register and which chip selects (one or all) are to be programmed. The user is expected to define mode register write data accurately. If the mode register number specified in WRMD bits [7:0] is not a valid setting for the memory system being used, the memory controller may exhibit unpredictable behavior.

34.5.53 Control Register 52 (DDRMC_CR52)

Address: 400A_E000h base + D0h offset = 400A_E0D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DDRMC_CR52 field descriptions

Field	Description
31–24 Reserved	This read-only field is reserved and always has the value 0.
23–16 MR17_DA0	Holds the memory mode register 17 data for chip select 0 written during memory initialization or when the WRMD bit [25] is asserted with bit [16] or bit [18] set to 1. The meaning of this parameter depends on the memory system being used: • For LPDDR2 memories: (MR17) for LPDDR2 S4 memories. If the lpddr2_s4 parameter is set to 1, the fields of MR17 will be programmed into the DRAM at initialization or when the WRMD is set to 1. • For DDR3 memories: This parameter has no meaning for this memory type.
15–8 MR16_DA0	Holds the memory mode register 16 data for chip select 0 written during memory initialization or when the WRMD bit [25] is asserted with bit [16] or bit [18] set to 1. The meaning of this parameter depends on the memory system being used: • For LPDDR2 memories: (MR16) The fields of MR16 will be programmed into the DRAM at initialization or when the WRMD bit is set to 1. • For DDR3 memories: This parameter has no meaning for this memory type.
7–0 MR8_DA0	Holds the memory mode register 8 (MR8) data for LPDDR2 memories for chip select 0 read during memory initialization. These parameters are read-only. The meaning of this parameter depends on the memory system being used: • For LPDDR2 memories: (MR8) The fields of MR8 will be read from the memories (LPDDR2-SDRAM) at initialization if the no_auto_mrr_init parameter is cleared to 0 or when the RMD bits are set to 1. • For DDR3 memories: This parameter has no meaning for this memory type.

DDRMC_CR58 field descriptions

Field	Description
31–25 Reserved	This read-only field is reserved and always has the value 0.
24 ECC_DIS_ WCRER	Disables automatic corruption of the ECC codes for an entire user word when the read portion of a read/modify/write operation has an un-correctable error. If this is not disabled, the corruption will occur even if the erroneous byte is overwritten with new data. 0 Allow the ECC codes for the entire user word to be corrupted. (Default) 1 Disable the corruption. The ECC codes written to memory will match the new write data written to memory.
23–22 Reserved	This read-only field is reserved and always has the value 0.
21–8 XOR_CHK_BITS	When the fwc parameter is set, the check bits generated by the next write operation will be XOR'ed with this parameter. The result will be written into memory as the new check value.

Table continues on the next page...

DDRMC_CR58 field descriptions (continued)

Field	Description
	• xor_chk_bits [13:7] maps to user word [63:32] • xor_chk_bits [6:0] maps to user word [31:0]
7–1 Reserved	This read-only field is reserved and always has the value 0.
0 FWC	Forces a write check. When this bit is set, the memory controller will XOR the xor_check_bits parameter with the generated checksum bits from the next word to be written to the memory. This parameter is write-only and will always read back as 0x0. Once the next write operation has been completed, the memory controller will automatically clear this bit to 0. 0 No action. 1 Force a write check.

34.5.60 Control Register 59 (DDRMC_CR59)

Address: 400A_E000h base + ECh offset = 400A_E0ECh

DDRMC_CR64 field descriptions

Field	Description
31–0 ECC_C_DATA	Contains the pre-corrected data associated with a single bit correctable ECC event. This parameter will only be used when a correctable error occurs and ECC error reporting is enabled in the ctrl_raw parameter.

34.5.66 Control Register 65 (DDRMC_CR65)

Address: 400A_E000h base + 104h offset = 400A_E104h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DDRMC_CR65 field descriptions

Field	Description
31–30 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
29–16 ECC_C_ID	Contains the source ID associated with a single bit correctable ECC event. This parameter will only be used when a correctable error occurs and ECC error reporting is enabled in the ctrl_raw parameter.
15–13 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
12–0 ECC_U_ID	Contains the source ID associated with a double bit un-correctable ECC event. This parameter will only be used when an un-correctable error occurs and ECC error reporting is enabled in the ctrl_raw parameter.

34.5.67 Control Register 66 (DDRMC_CR66)

Address: 400A_E000h base + 108h offset = 400A_E108h

Bit	31–28	27–16	15–12	11–0
R	0	ZQCL	0	ZQINIT
W				
Reset	0 0 0 0	0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0	0 0 0 0 0 0 0 0 0 0 0 0

DDRMC_CR66 field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–16 ZQCL	Specifies the duration of wait time, in memory clocks, required for the memories to complete a long ZQ calibration command (ZQCL). This parameter is only applicable when the MC is programmed for the following memory systems: • LPDDR2 (dram_class = ’b0101) • DDR3 (dram_class = ’b0110)
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–0 ZQINIT	Specifies the duration of wait time, in memory clocks, required for the memories to complete a ZQ command during initialization. This parameter is only applicable when the MC is programmed for the following memory systems: • LPDDR2 (dram_class = ’b0101) • DDR3 (dram_class = ’b0110)

34.5.68 Control Register 67 (DDRMC_CR67)

Address: 400A_E000h base + 10Ch offset = 400A_E10Ch

Bit	31–28	27–16	15–12	11–0
R	0	0	0	ZQCS
W				
Reset	0 0 0 0	0 0 0 0 0 0 0 0 0 0 0 0	0 0 0 0	0 0 0 0 0 0 0 0 0 0 0 0

DDRMC_CR67 field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–16 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
15–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
11–0 ZQCS	Specifies the duration of wait time, in memory clocks, required for the memories to complete a short ZQ calibration command (ZQCS). This parameter is only applicable when the MC is programmed for the following memory systems: • LPDDR2 (dram_class = ’b0101) • DDR3 (dram_class = ’b0110)

34.5.69 Control Register 68 (DDRMC_CR68)

Address: 400A_E000h base + 110h offset = 400A_E110h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DDRMC_CR69 field descriptions

Field	Description
31–12 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DDRMC_CR69 field descriptions (continued)

Field	Description
11–8 ZQ_ON_SREF_EX	Issues a ZQ command when exiting selfrefresh mode. This is a one-hot parameter which determines the type of operation performed on self-refresh exit. **NOTE:** It is recommended to set this parameter to execute a ZQCL on selfrefresh exit. By setting this parameter this way, a ZQCL will be issued before any other commands are permitted to execute. If this parameter is programmed to any other setting, the system must manage self-refresh exit and ZQ calibration. If using the ZQCS option, it is advised that the rotate function should be disabled (the parameter zqcs_rotate should be cleared to 0) to calibrate all chip selects. • Bit [3] — Triggers a ZQ reset to all chip selects in the system on self-refresh exit. (This bit is only applicable for LPDDR2 memory systems) • Bit [2] — Triggers a ZQ initialization to all chip selects in the system on selfrefresh exit. (This bit is only applicable for LPDDR2 memory systems) • Bit [1] — Triggers a long ZQ calibration to all chip selects in the system on selfrefresh exit. • Bit [0] — Triggers a short ZQ calibration. If the zqcs_rotate parameter is set to 1, only one chip select will be calibrated (in round-robin fashion). If the zqcs_rotate parameter is cleared to 0, all chip selects defined in the parameter cs_map will be calibrated. This parameter is only applicable when the MC is programmed for the following memory systems: • LPDDR2 (dram_class = ’b0101) • DDR3 (dram_class = ’b0110)
7–4 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
3–0 ZQ_REQ	Triggers a user-requested ZQ operation. This parameter is write-only and will always read back as 0x0. • Bit [3] — Triggers a ZQ reset to all chip selects in the system. (This bit is only applicable for LPDDR2 memory systems) • Bit [2] — Triggers a ZQ initialization to all chip selects in the system. (This bit is only applicable for LPDDR2 memory systems) • Bit [1] — Triggers a long ZQ calibration to all chip selects in the system. • Bit [0] — Triggers a short ZQ calibration. This parameter is only applicable when the MC is programmed for the following memory systems: • LPDDR2 (dram_class = ’b0101) • DDR3 (dram_class = ’b0110)

34.5.71 Control Register 70 (DDRMC_CR70)

Address: 400A_E000h base + 118h offset = 400A_E118h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	REF_PER_ZQ																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_CR70 field descriptions

Field	Description
31–0 REF_PER_ZQ	Sets the maximum number of refreshes allowed between automatic ZQCS commands. Setting this parameter to 0x0 will disable automatic ZQCS commands. When using the rotate option (the parameter zqcs_rotate is set to 1), this parameter should be programmed to the total number of controller clocks desired between ZQCS commands divided by the number of chip selects in the system.

DDRMC_CR70 field descriptions (continued)

Field	Description
	This parameter is only applicable when the MC is programmed for the following memory systems: • LPDDR2 (dram_class = ’b0101) • DDR3 (dram_class = ’b0110)

34.5.72 Control Register 71 (DDRMC_CR71)

Address: 400A_E000h base + 11Ch offset = 400A_E11Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DDRMC_CR71 field descriptions

Field	Description
31–20 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
19–8 ZQRESET	Specifies the duration of wait time, in memory clocks, required for the memories to complete a ZQRESET command.

Table continues on the next page...

DDRMC_CR71 field descriptions (continued)

Field	Description
	This parameter is only applicable when the MC is programmed for the following memory systems: LPDDR2 (dram_class = ’b0101)
7–1 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
0 ZQ_IN_PROG	Indicates that a ZQ command is currently in progress. If a ZQ command is requested while this parameter is set to 1, the new ZQ request will be ignored. This parameter is read-only. • 0 — Not in progress • 1 — In progress

34.5.73 Control Register 72 (DDRMC_CR72)

Address: 400A_E000h base + 120h offset = 400A_E120h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_CR72 field descriptions

Field	Description
31–25 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
24 ZQCS_ROTATE	Defines the behavior of short ZQ calibrations. If this parameter is set to 1, a ZQCS request will only be issued to one chip select on each request, regardless of the source of the request. The MC will maintain a counter such that the chip selects are calibrated in a fixed rotating sequence. 0 = Calibrate all chip selects on each ZQCS request. 1 = Calibrate only one chip select on the next ZQCS request. This parameter is only applicable when the MC is programmed for the following memory systems: • LPDDR2 (dram_class = ’b0101) • DDR3 (dram_class = ’b0110)
23–17 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

Table continues on the next page...

DDRMC_CR72 field descriptions (continued)

Field	Description
16 NO_ZQ_INIT	Disables ZQ operations during initialization. 0 = ZQ operations allowed during initialization. 1 = ZQ operations disabled during initialization. This parameter is only applicable when the MC is programmed for the following memory systems: • LPDDR2 (dram_class = 'b0101)
15–0 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.

34.5.74 Control Register 73 (DDRMC_CR73)

Address: 400A_E000h base + 124h offset = 400A_E124h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DDRMC_CR73 field descriptions

Field	Description
31–28 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
27–24 APREBIT	Defines the location of the auto precharge bit in the DRAM address in decimal encoding. **NOTE:** This parameter will be cleared to 0x0 on reset, but will change to the default value on the first controller clock edge after reset.
23–19 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
18–16 COL_DIFF	Shows the difference between the maximum column width available (11) and the actual number of column pins being used. The user address is automatically shifted so that the user address space is mapped contiguously into the memory map based on the value of this parameter.
15–10 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
9–8 ROW_DIFF	Defines the difference between the maximum number of address pins configured (16) and the actual number of pins being used. **NOTE:** For DDR3 memory systems (dram_class = 'b0110), this parameter should reflect the difference in the number of address pins configured and the number of row pins being used. **NOTE:** For LPDDR2 memory systems (dram_class = 'b0101), this parameter holds the difference between the maximum number of row pins configured and the actual number of row pins being used for chip select X.

Table continues on the next page...

DDRMC_CR73 field descriptions (continued)

Field	Description
7–2 Reserved	This field is reserved. This read-only field is reserved and always has the value 0.
1–0 BANK_DIFF	Defines the difference between the maximum number of banks configured (3) and the actual number of banks being used. 00 All bank bits are being used (8 banks) 01 Only 2 bank bits are being used (4 banks) 10 Only 1 bank bit is being used (2 banks) 11 Reserved

34.5.75 Control Register 74 (DDRMC_CR74)

Address: 400A_E000h base + 128h offset = 400A_E128h
